Engineering Reviews: In-Depth Review of Major Impact Measures

Table I-1: Summary List of In-Depth Review of Major Impact Measures

Section #	Measure Group	Measure Name	Engineering Realization Rate
1	Building Shell	Greenhouse Heat Curtain	85%
2	Building Shell	Window Film	80%
3	HVAC-Other	Programmable Thermostats	kWh = 2.4% Therm = 1.9%
4	HVAC-Other	VSD – AHU	100%
5, 6, 7	Lighting-CFL	CFL	* See Logger Analysis
8	Lighting-Other	HiBay T5	* See Logger Analysis
9	Lighting-Other	LED Exit Sign	100%**
10	Lighting-Other	Occ-Sensor - HighBay	100%**

^{*} No adjustment made to the work paper savings estimates.

I.1 Greenhouse Heat Curtains

I.1.1 Summary

Work Paper Savings Estimates: 0.39 therms/sq. ft./year

■ New Estimated Savings: 0.31 therms/sq. ft./year

Engineering Adjustment Factor: 0.80

Measure Cost: \$0.49/sq. ft.Measure Life: 5 years

I.1.2 Prior Savings Estimates

The work paper indicates the savings estimate was based on usage of a prototypical 4,000 sq. ft. warehouse with Southern California Gas customer characteristics (based on 2001 Express Efficiency participants). No further detail is provided. The savings estimates for the current work papers are undocumented. Itron was able to obtain some detail on savings estimates for the 2001 Express Efficiency program. However, these calculations did not appear to be the source of the estimates in the 2004 work papers.

I.1.3 New Savings Estimates

Without additional information and details on the sources of the energy savings estimate for this measure, Itron is unable to verify or refute the estimate. A research of savings estimates for similar measures in other energy incentive programs show that in a case study of a Wisconsin project, energy savings resulting from the installation of heat curtains in a 70,000 sq. ft. greenhouse facility yielded energy savings of 0.17 therms/sq. ft./year. Based on climate considerations, the PY 2004/2005 work paper estimate, although smaller than the savings estimate used in the 2001 Express Efficiency program, may still be high.

Note that the savings estimates are expected to depend heavily on the location and climate zone and the type of growing environment. In addition, in order for the energy savings to be realized, the curtains must be properly and consistently operated.

Thermal curtains have additional uses aside from night insulation, and construction of curtains can vary depending on the expected usage (e.g., daytime shading verses only nighttime usage).

Curtains offered primarily for insulation can reduce energy by 50%, while porous materials used for both insulation and shade protection can reduce winter usage by 25-30%. (Roberts, *Put a Lid on Heating Costs with Thermal Screens*, 2000). Conversations with some utility representatives indicate that some greenhouse heat curtains may not be consistently deploying the curtains during night hours, as is necessary to save on gas heating energy. A

survey of customer may be necessary to determine whether the curtains are being used as intended.

I.1.4 Discussion of Relevant Variables

Relevant variables are not explicitly identified but are believed to be baseline and proposed radiation and convection losses, temperatures maintained in the greenhouse, climate zones, type of heat curtain material and the percentage of time deployed. Orientation of the surface (roof or walls) may also be important.

I.1.5 Work Paper Assumptions

Significant assumptions are not explicitly identified.

I.1.6 Work Paper Equation

The equation employed is not known.

I.1.7 Recommendations

Based on the size of this measure relative to other measures, we recommend on-site verifications and interviews to determine the energy savings. On-site data collection is recommended so that it can be determined how greenhouse heat curtains are used.

There are only three (3) participants in PY2004/PY2005, so phone surveys to all participants and "verification only" on-sites for the three installations should be conducted.

Variables to be collected, their relative usefulness, and the method of data collection are defined in the following table. Underlined values denote the recommended approach given the projected overall efficacy of the collection method.

Table I-2: Collection Methods for Greenhouse Heat Curtains

			Collection	Method		Use in	
Variable	Value	Secondary	Survey	On-Site	M&V	Equation	Source of Data
Туре	Med	Low	Med	High	na	n/a	Survey Questions; Verifier observations
Air Space	Med	Low	Med	High	na	n/a	Survey Questions; Verifier observations
Day/Night Use	High	Low	Med	High	na	n/a	Survey Questions; Verifier observations
Seasonal Use	High	Low	Med	High	na	n/a	Survey Questions; Verifier observations
Efficacy		Low	Med	<u>High</u>	NA		

I.1.8 Results

The engineering realization rate was 80% and was adjusted according to the unweighted average of the hours of daily operation verses the estimated 11 hours of expected operation upon which the work paper estimates are believed to be based. Using the weighted average affects the realization rate slightly. Seasonal use was incorporated in these hourly estimates of use. The air space thickness and materials were not used in calculations since it is uncertain without sophisticated modeling how these variables affect radiation and convection/conduction. The type of material was polyethylene/nylon and was in good to excellent condition. Based on these findings, the five-year estimate of life may underestimate the true useful life. The cost per square foot estimate appears reasonable.

Table I-3: Summary of Green House Curtains

# of Sites Used in Engineering Analysis	3
Rebated (sq.ft)	116,583
Verified (sq.ft)	47,312
WP Hours deployed/yr	4,015
Hours deployed/yr	3,205
WP Savings per sq.ft(therms)	0.39
Savings per sq.ft(therms)	0.31
Engineering Realization Rate	85%

I.2 Window Film

I.2.1 Summary

■ Work Paper Savings Estimates: 14.31 kWh/sq. ft. average for 8 climate zones (4.14 to 23.79 kWh/sq. ft./year depending on climate zone)

■ New Estimated Savings: 11.46 kWh/sq. ft. average

■ Engineering Adjustment Factor: 0.80

Measure Cost: \$3.12/sq. ft.Measure Life: 10 years

I.2.2 Prior Savings Estimates

The basis of the reflective window film measure savings are simulations run using the California New Construction Calculator (CaNCcalc) 2001. This software uses DOE-2 as the calculation engine to assess the potential energy savings. The CaNCcalc simulation process begins by automatically developing a DOE-2 "model" of the building based on user selections. The base line is a DOE-2 building model that assumes a minimum level of efficiency (e.g., minimally compliant with California Title24 or ASHRAE 90.1). Input to DOE-2 consists of a detailed description of the building being analyzed, including hourly scheduling of occupants, lighting, equipment, and thermostat settings. DOE-2 provides very accurate simulation of such building features as shading, fenestration, interior building mass, envelope building mass, and the dynamic response of differing heating and air conditioning system types and controls. DOE-2 also contains a dynamic daylighting model to assess the effect of natural lighting on thermal and lighting demands. The following assumptions are used for the reflective window film simulations:

- **B** Base case windows are single-pane, and SHGC = 0.95.
- The simulated window shall have SHGC = 0.39.
- Small retail and small office building types shall be used as the model for Express Efficiency program savings.
- The window-to-wall ratio for building types shall be 0.20.
- Building areas for purposes of this analysis shall be defaulted at 8,000 sq. ft.
- Buildings shall be studied for all California Thermal Zones (CTZ) located in the utility service territory.

DOE-2 is an industry standard software tool that has been validated, and is widely accepted for component savings calculations so the calculations themselves will not be repeated in this evaluation. The assumptions that go into the simulation will be examined.

I.2.3 New Savings Estimates

The new savings were estimated based upon formula below and the solar gain for directions in which the retrofit glass faced. The solar insulation data was taken from ASHRAE and from Entergy for a representative California latitude. An alternative method would be to run DOE 2 simulation models for each of the sites visited.

Table I-4:	Annual	Solar	Heat	Gain	Factor	(SHGF))
------------	--------	-------	------	------	---------------	--------	---

Orientation	(Btu/ft2-year)
SE	158,323
SSE	133,894
S	120,095
SSW	133,894
SW	158,323
WSW	168,978
W	162,388
WNW	139,995
NW	106,876

A coefficient of performance (COP) of 2.7 and a pre retrofit solar heat gain coefficient (SHGC) of 0.95 were used. The shading coefficients (SCs) were determined from the solar heat gain coefficients and the following formula was applied for each section of glass facing in each direction:

$$kWh\ savings = (Area \times SHGF \times (SC\ pre - SC\ post))/(3413 \times COP)$$

The method used is more accurate than the method used in the work paper as the work paper is believed to have modeled savings based on typical small retail buildings with walls facing only in cardinal directions (North, South, East, and West).

If DOE2.2 or the new construction calculator are used it should be noted that some assumptions are incorrect. ASHRAE Fundamentals 2005 reports Solar Heat Gain Coefficient (SHGC) equal to 0.81 for single pane clear glass with a SC of 0.94.

The assumption for new representative SHGC factors is correct. The National Fenestration Rating Council (NFRC) maintains a directory of certified fenestration products. The products must be tested by an independent laboratory in order to be included in the database. Only one window film manufacturer (of 7 manufacturer members listed on the International Window Film Association website) has products listed in the database. The range of SHGC

for the 15 products listed is 0.19 to 0.45 when the film is applied to one-eighth inch clear glass, and from 0.23 to 0.49 when the film is applied to one-quarter inch clear glass (a more typical installation). The average SHGC is 0.35 for one eighth inch glass and 0.39 for one-quarter inch glass.

As noted, small retail and small office building types were used for the simulation. Details of the building configuration were not able to be obtained. The building configuration variables that affect the window film simulation are exterior shading and the building air conditioning operating schedule. The assumption for building type appears reasonable. However, the assumption of the window to wall ratio is 0.20. This parameter is important to the analysis as it relates directly to the magnitude of solar gain. The wall-window ratio varies greatly from 0.12 for most residences to 0.75 for high-rise office buildings. More research is needed on the types of buildings that participate in the Express Efficiency program.

The building area is set at 8000 square feet for the simulation analysis. This parameter is also important to the analysis as it affects the ratio of window area to floor area. The results are reported on a per floor area basis so the window area to floor area ratio strongly affects the result. More research is needed on the types of buildings that participate in the Express Efficiency program.

Assumption f: The climate zones modeled are those in SCE territory. Climate zones 1-5, 7, and 11-12 are not modeled and no savings are reported for these climate zones. These climate zones should be modeled if window film rebates are to be given in these climate zones. There will be a significant difference in savings between the southern California zones modeled and northern California zones that were not modeled.

The source of the installed cost and measure lifetime figures are documented, and appear reasonable.

I.2.4 Discussion of Relevant Variables

Relevant variables are only identified as the solar heat gain coefficients. The directions of widows and the building characteristics are not explicitly identified in the models used. However, the retrofit window directions, areas, and shading coefficients (where able to be determined for specifications and cut sheets) were used. Climate zones and periods of time when air conditioning is not used (e.g., in schools in summer or offices on weekends) may also be important.

I.2.5 Work Paper Assumptions

Significant assumptions are not explicitly identified except for solar heat gain coefficients as noted above.

I.2.6 Work Paper Equation

The equations employed in the model are not known, but are believed to be similar to that used in the ex post analysis.

I.2.7 Recommendations

We recommended and used on-site verifications and interviews to determine the energy savings. On-site data collection is recommended so that the exact directions and shading effects from buildings and trees can be determined, as well as collecting information on the window films.

Variables to be collected, their relative usefulness, and the method of data collection are defined in the following table. Underlined values denote the recommended approach given the projected overall efficacy of the collection method.

Table I-5: Collection Methods for Window Film

		C	ollection M	Iethod		Use in	
Variable	Value	Secondary	Survey	On-Site	M&V	Equation	Source of Data
Window treatments (shades, etc.)	Med	Low	Low	Med	Na	Affects Area or SC	Survey Questions; Verifier observations
Type of film (SC value)	Med	Low	Low	Med	Na	Affects SC (post)	Survey Questions; Shipments/Invoice s/ Cut Sheets
Size of area treated by orientation (N,S,E,W)	Med	Low	Low	High	High	Area	Survey Questions; Verifier observations
Exterior shading	Med	Low	Low	High	Na	Affects Area	Verifier observations
Efficacy		Low	Low	<u>High</u>	High		

I.2.8 Results

The engineering realization rate was 80% and was adjusted according to the unweighted average of the savings estimates by climate zones upon which the work paper estimates are based. Using the weighted average may affect the realization rate slightly but should be adjusted by the population. The calculated savings are also presented as an unweighted average savings and were calculated as described in the above sections. The engineering

realization rate could be lower based on two factors which were not quantified for this evaluation: 1) the reduced weekend use of air conditioning equipment, and 20 the use of blinds and internal shades prior to and after the retrofit.

The type of films varied, and it is believed that the ten year estimate of life may underestimate the true useful life. The cost per square foot estimate appears reasonable.

Table I-6: Summary – Window Film

# of Sites Used in Engineering Analysis	12
Window Film Area rebated (sq.ft)	5930
Window Film Area verified (sq.ft)	5287
WP SHGC	0.39
SHGC	0.34
Average WP Savings kWh/sq.ft	14.31
Calculated Savings kWh/sq.ft	11.46
Engineering Realization Rate	80%

I.3 Programmable Thermostats

I.3.1 Summary

■ Work Paper Savings Estimates: 4,093 kWh/year; 1,095 therms/yr

■ New Estimated Savings: 99 kWh/year; 21 therms/yr

■ Engineering Adjustment Factor: 0.02

Measure Cost: \$58Measure Life: 11 years

I.3.2 Prior Savings Estimates

A summary of significant assumptions that require qualification is as follows:

- San Jose weather data are taken as representative of the entire state.
- Average size of unit(s) controlled by one programmable thermostat is 10 tons for direct expansion (DX) air conditioning and 250 MBH for heating (capacities estimated for a 5,000 sq. ft. building).
- All heating is by natural gas.
- No outside air economizers are in use and outside air is fixed at 20%.

- The baseline assumes that temperature is maintained by using a setpoint of 72°F to 74 F year round and throughout each day/week (return air temperature is listed as 74 F).
- Occupied hours are Monday thru Friday 7 a.m. to 6 p.m.
- Energy use is calculated based on dry bulb verses wet bulb temperatures for cooling conditions (ignores latent heat removal/dehumidification).
- Fan operation may be assumed to be continuous and fan savings were conservatively neglected.
- The supply air temperature is consistent with an average supply air temperature. The compressor would actually cycle in a DX system so an alternate method to calculate savings would be based on reduced hours of compressor run time and a constant supply air temperature across all bins for cooling (except perhaps in the case of variable speed compressors not typical on this size of equipment).

In addition to these assumptions, the work paper analysis used improper return air temperatures for the unoccupied hours during which temperatures were adjusted upwards or downwards. The return air temperature was shown as 74 F. However, during these hours, the space and thus return air temperatures should approximate the setback or setup temperatures (assumptions are consistent with 55 F and 85 F, although these are not stipulated in the analysis). A useful caveat is that, although the adjusted temperatures may be 55 F and 85 F, the building may not reach these temperatures due to internal heat gain and heat storage in the building. Thus, it may be more appropriate to use setback and setup temperatures of 60 F and 80 F, dependent on the building and its characteristics.

The PY2004 /PY2005 work paper did not take into account the adjustments suggested in the evaluation of the 1997 program cited above. The 1997 evaluation (Attachment 2-1) suggested higher heating savings and lower cooling savings by approximately 10% (4,664 kWh/yr and 909 therms/yr) for a 10-ton unit with 250 MBH of heating capacity serving a 5,000 sq. ft. building.

More importantly, the evaluation suggested adjusting the energy impacts by actual conditioned area using the same sizing criteria for cooling and heating capacities (essentially this adjustment could be performed by using the actual equipment capacities). Actual savings will depend on the size of the unit controlled.

Equally important, the evaluation showed that there is very significant variation in kWh savings per ton between the 16 climate zones (using binned data for each zone). Actual savings will depend on the climate zone where the units are controlled, and can vary by 13% to 436%, with an average variation across all 16 regions of 149%. This variation is borne out by comparing the cooling degree day data (base 65 F) for all 16 zones. The work paper

specifically notes that savings may vary significantly higher and lower than the estimates provided.

I.3.3 New Savings Estimates

Hours, setback temperatures, heating and/or cooling use, and building area were used to establish proportions of the stipulated work paper savings. Another method would be to average the input variables and apply either the work paper methodology or the equation below and an additional formula for electric resistance heating.

I.3.4 Discussion of Relevant Variables

Relevant variables are area, air flow (cfm), temperature differences, hours of operation, and the percentage of air treated. Other variables are the presence of heating and/or cooling, and climate zone.

I.3.5 Work Paper Assumptions

Significant assumptions are identified in previous sections

I.3.6 Work Paper Equation

Although not specifically called out, the underlying calculations are:

Heating or cooling Btu = Q = ASHRAE bin hours x cfm x 1.1 x delta T

Electric and gas savings are then derived using efficiency values for the heating and cooling components.

I.3.7 Recommendations

Based on the size of this measure relative to other measures, we recommend on-site surveys to determine the energy savings. On-site data collection is recommended so that an accurate estimate of typical connected load, hours and settings. Data collection and M&V activities should be considered for this measure to get accurate estimates of reduced run time of equipment and unoccupied cycles.

Secondary sources such as DEER and CEUS data were considered for determining operating hour reductions. However, these data sources will likely not provide accurate estimates of connected load.

Data collected will be analyzed and values used to generate estimates of energy savings according to the methodologies contained in the work papers. Alternate methodologies would be developed if, on further review and with data collected, savings estimates appear to

be either understated or overstated. For instance, for electric baseboard heating control, the work paper equations and methodology would not be accurate.

A preliminary assessment was that the overall benefits of programmable thermostats are overstated and should be approximately 20% of the work paper estimates. This conforms to an average unit size of 2 tons and a heating capacity of 25 MBH, with a controlled area of 500 sq. ft.

Evaluation should be conducted on a size (unit capacity or square foot of area served in square feet) basis and possibly on a utility or climate zone basis. Adjustment shall be performed using the average data from each climate zone obtained from the 1999 study cited above as well as adjustment for the average area served or size factor obtained from the installation records.

Variables to be refined include the following:

- Size of the unit in cooling (tons) and heating capacity (MBH)
- Heat source (gas or electric or other)
- Climate zone where the unit is located
- Operation of units previous to thermostat installation (e.g., was system manually adjusted, was there another type of programmable thermostat or other control system in place, etc.)
- Temperature maintained previously during occupied and unoccupied hours
- Time and temperature settings for unoccupied hours
- Presence of locking covers
- Presence of override features and percent of time used
- Percent of outside air being brought in through outside air dampers as a percent of total air
- Use of any outside air economizers
- Supply fans on automatic setting or left running continuously during the unoccupied hours

Variables to be collected, their relative usefulness, and the method of data collection are defined in the following table. Underlined values denote the recommended approach given the projected overall efficacy of the collection method

Table I-7: Collection Methods for Programmable Thermostats

		Collection Method				Use in			
Variable	Value	Secondary	Survey	On-Site	M&V	Equation	Source of Data		
Connected load (Size and type of heating/cooling controlled)	High	Low	Med	Med	N/A	Determines cfm of outside air	Survey questions; Verifier observations; query site maintenance staff		
Operating hours	Med	Med	Med	Med	N/A	Determines actual bin hours	Survey questions; Verifier observations; query site management/maint enance staff		
Programmed hours	High	Low	Med	Med to High	High	Determines percent of bin hours in unoccupied modes	Survey questions; Verifier observations; query site management/maint enance staff; temp loggers		
Occupied/ unoccupied temperature settings	High	N/A	Med	High	High	Determines delta temperature	Survey questions; Verifier observations; query site management /maintenance staff; temp loggers		
Locking cover in place and used	Med	N/A	Low	High	N/A	Determines persistence of savings over time (bin hours) unoccupied mode is in effect	Verifier observations; query site maintenance staff		
HVAC system efficiency	Low	Low	Med	Med	N/A	Direct translation of heat loss/gain to electric/gas savings	Verifier observations; query site maintenance staff		
Geographic	Med	High	High	High	N/A	Affect bin	Query of Utility		

Location					hours	tracking data
Efficacy	Low	Low	Med	<u>High</u>		

¹ Values given for various collection methods relate the relative accuracy of data collected for a given variable.

I.3.8 Results

The engineering realization rate was about 2% for electric and gas savings. The percentages were because the size of area controlled was smaller, typically involved electric or gas savings but not both, and that many of the thermostats were not programmed to adjust the temperatures.

Itron recommends a substantial revision work of the calculations supporting the programmable setback thermostats and incentives. This revision should be based upon actual sizes and operation as discovered in the field. The revision may be best based upon energized time factors for various components. This method would then be based upon the fact that the unit space conditioning capacity would be energized at different percentages for different ambient conditions, and rely on the proper sizing of the unit verses variable factors such as type and size of building, location of zone being controlled, and amount of outside air used.

Table I-8: Summary of Programmable Thermostats

# of Sites Used in Engineering Analysis	38
Thermostats rebated	1319
Thermostats verified	1509
WP Savings/thermostat (therms/yr)	1095
Savings/thermostat (therms/yr)	21
WP Savings/thermostat (kWh/yr)	4093
Savings/thermostat (kWh/yr)	99
Engineering Realization Rate (therms)	1.9%
Engineering Realization Rate (kWh/yr)	2.4%

Note that if programmable thermostats were programmed, it was calculated that the realization rates would increase to 21% for gas and 54% for electric savings.

The 11-year estimate of life may overestimate the true useful life. The cost per thermostats of \$58 appears reasonable.

² M&V refers to engineering activities including temperature sensor and AC equipment cycling studies: on sites includes primarily verification and settings of installed equipment

I.4 Variable Speed Drives (VSDs) - AHUs

I.4.1 Summary

Work Paper Savings Estimates: 753 kWh/hp/year

New Estimated Savings: 753 kWh/hp/year

■ Engineering Adjustment Factor: 1.00

Measure Cost: \$202/hpMeasure Life: 15 years

I.4.2 Prior Savings Estimates

The work paper indicates the savings estimate was based building simulations using DOE2.1D with a fan efficiency of 1.25 watts/cfm, an air flow of 0.75 cfm/sq. ft. and an average savings coefficient of 1.33. The work paper also cites the use of an inlet vane system for a base case and reduces the savings to 81% of the total savings forecast by DOE 2.1D.

I.4.3 New Savings Estimates

Without additional verification of the input parameters, Itron is unable to verify or refute the estimate. However, based on an independent alternate calculation with usage of the fan at 2,000 hours per year (typical for an office building) and 80% speed (corresponding to 50% power reduction), the ex ante savings forecast appears reasonable. The exact hours or load reduction throughout the year were unable to be determined for many of the installations. However, some spot readings and operator interviews did support the energy savings using the alternate calculation. For this reason, the equations used in the work papers were used for the ex post savings estimate.

I.4.4 Discussion Of Relevant Variables

Relevant variables in the work paper are a fan efficiency of 1.25 watts/cfm, an air flow of 0.75 cfm/sq. ft. and an average savings coefficient of 1.33. The work paper also cites the use of an inlet vane system for a base case and reduces the savings to 81% of the total savings. These variables are hard to quantify and can vary considerably. In the alternate calculation, the hours and load (speed) are easier to quantify, but may also vary considerably.

I.4.5 Work Paper Assumptions

Significant assumptions are identified in the previous sections.

I.4.6 Work Paper Equation

The equation employed in the work paper is as follows:

kWh/yr saved = 1.25 w/cfm xx 746 w/hp x 0.75 cfm/sq. ft. x 1.33 savings coefficient x 81%

I.4.7 Recommendations

Based on the size of this measure relative to other measures, we recommend on-site verifications and interviews to determine the energy savings. On-site data collection is recommended so that it can be determined how the VSDs are actually used.

Variables to be collected, their relative usefulness, and the method of data collection are defined in the following table. Underlined values denote the recommended approach given the projected overall efficacy of the collection method.

Table I-9: Collection Methods for Variable Speed Drives – AHUs

			Collection	Method		Use in	Source of
Variable	Value	Secondary	Survey	On-Site	M&V	Equation	Data
Size	High	Med	Med	High	N/A	Direct input for verification	Survey Questions; Verifier observations
% of time on	High	Low	Med	High	High	Direct input (in alternate equation)	Survey Questions; Verifier observations; M&V
% loaded	High	Low	Low	Med	High	Direct input (in alternate equation)	Survey Questions; Verifier observations; M&V
Efficacy		Low	Low	Med	<u>High</u>		

¹ Values given for various collection methods relate the relative accuracy of responses for a given variable.

I.4.8 Results

The engineering realization rate was 100% reflects the fact that it was not possible to adjust the ex ante prior savings estimates based on data from the field. The verification rate is significantly higher, due to the many air handling units encountered and the uncertainty of site personnel regarding the exact units for which incentives were paid.

² M&V refers to primarily to current sensors and loggers.

I.5 Compact Fluorescent Lamps (CFLS), 5-13 Lamp Watts

I.5.1 Summary

■ Work Paper Savings Estimates: 111 to 302 kWh/yr; 0.023 to 0.047 kW

New Estimated Savings: See Lighting Logger Analysis

■ Engineering Adjustment Factor: See Lighting Logger Analysis

■ Measure Cost: \$ 18.13 /unit (based on discounted rates)

■ Measure Life: 32,000 hours, 7.7 years (average)

I.5.2 Prior Savings Estimates

The work paper indicates the savings estimate was based on usage and formulas shown below, with a non-coincident demand reduction of 0.045 kW.

Table I-10: CFL Lamps, 5-13 Watts, Energy and Demand Interactive Effects by Market Sector

Market Sector	Energy Interactive Effects	Demand Interactive Effects
Office	1.17	1.25
Retail	1.11	1.19
College	1.15	1.22

All Other	4,500	0.76	0.039	219

I.5.3 New Savings Estimates

See Lighting Logger Analysis.

I.5.4 Discussion of Relevant Variables

The energy savings resulting from the installation CFL fixtures is dependent on three main factors: operating hours, baseline demand, and installed demand. Of these factors, the operating hours tend to introduce the most uncertainty into the calculations. M&V studies tend to produce the best approximation of operating hours, although interview data can be helpful in estimating hours when more detailed data is not available.

I.5.5 Work Paper Assumptions

In addition to the above, below is a summary of significant assumptions:

- Savings are based on a 13-watt CFL (0.015 kW), and
- The CFL replaces a 60-watt incandescent lamp.

Energy interactive effects are also defined per market sector and assume a cooling system efficiency and factor. The efficiency used and the source of these factors are not transparent.

I.5.6 Work Paper Equations

The following formula is used to estimate energy savings:

The following formulas are used to estimate demand savings for this measure:

Non-coincident kW reduction with Interactive Effects = (kW of existing equipment - kW of replacement equipment) * (Demand Interactive Effects)

Coincident kW Reduction = Coincident Diversity Factor

× Noncoincident reduction with Demand Interactive Effects

I.5.7 Recommendations

Based on the size of this measure relative to other measures, we recommend on-site verifications and interviews to determine the energy savings. On-site data collection is recommended so that an accurate estimate of typical wattages of the new fixtures can be determined. Data collection (M&V) activities with lighting loggers should be conducted to determine hours. However, due to the diverse nature of the locations where CFLs can be located, many different locations at a few sites with the same commercial or industrial end use (or SIC code) should be selected.

Secondary sources such as DEER and CEUS data may be valuable for determining pre retrofit and post retrofit wattages and operating hours.

Variables to be collected, their relative usefulness, and the method of data collection are defined in the following table. Underlined values denote the recommended approach given the projected overall efficacy of the collection method.

Table I-12: Collection Methods for CFLs Lamps, 5-13 Watt

		(Collection	Method		Use in	
Variable	Value	Secondary	Survey	On-Site	M&V	Equation	Source of Data
Connected load including ballasts losses	Low	High (from manu- facturers)	Low	Low	N/A	Direct input (delta watts) to savings	Manufacturer documentation; Verifier observations
New wattage	High	Med	Med	High	N/A	Direct input (delta watts) to savings	Utility tracking system; Survey questions; Verifier observations; query site management/m aintenance staff
Replaced wattage	High	Low	Med	Med	N/A	Direct input (delta watts) to savings	Survey questions; Verifier observations; query site management/m aintenance staff; inspect other non-replaced lamps
Operating hours	High	Low	Med	Low	High	Direct input (delta hours) to savings	Survey questions; Verifier observations; query site management/m aintenance staff; light loggers
Failure Rate	Low	N/A	Med	Med	N/A	Impacts number of retrofits	Survey questions; Verifier observations; query site maintenance staff
Length of Time In Service	Low	Low	Med	Low	Low	Affects remaining life (savings)	Survey questions

Efficacy	Low	Low	Med	High	
-					

- Values given for various collection methods relate the relative accuracy of data collected for a given variable.
- 2 Underlined values denote the recommended approach given the projected overall efficacy of the collection method.
- 3 M&V refers to primarily to light logger studies (including on site verification of installed wattage).

I.5.8 Results

The 7.7-year estimate of life may overestimate the true useful life. The cost per unit of \$18.13 per unit seems high but may be accurate, depending on assumptions used in discounting the initial investment.

See Lighting Logger Analysis for updated savings estimates and verification/engineering adjustment factors.

I.6 Compact Fluorescent Lamps (CFLs), 14-26 Lamp Watts

I.6.1 Summary

- Work Paper Savings Estimates: 141 to 383 kWh/yr; 0.029 to 0.060 kW
- New Estimated Savings: See Lighting Logger Analysis
- Engineering Adjustment Factor: See Lighting Logger Analysis
- Measure Cost: \$ 26.72 /unit (based on discounted rates)
- Measure Life: 32,000 hours, 7.7 years (average)

I.6.2 Prior Savings Estimates

The work paper indicates the savings estimate was based on usage and formulae shown below, with a non-coincident demand reduction of 0.057 kW.

Table I-13: CFL Lamps, 14-26 Watts, Energy and Demand Interactive Effects by Market Sector

Market Sector	Energy Interactive Effects	Demand Interactive Effects

I.6.3 New Savings Estimates

See Lighting Logger Analysis.

I.6.4 Discussion of Relevant Variables

The energy savings resulting from the installation CFL fixtures is dependent on three main factors: operating hours, baseline demand, and installed demand. Of these factors, the operating hours tend to introduce the most uncertainty into the calculations. M&V studies tend to produce the best approximation of operating hours, although interview data can be helpful in estimating hours when more detailed data is not available.

I.6.5 Work Paper Assumptions

In addition to the above, below is a summary of significant assumptions:

- Savings are based on a 18-watt CFL (0.018 kW), and
- The CFL replaces a 75-watt incandescent lamp.

Energy interactive effects are also defined per market sector and assume a cooling system efficiency and factor. The efficiency used and the source of these factors are not transparent.

I.6.6 Work Paper Equations

The following formula is used to estimate energy savings:

The following formulas are used to estimate demand savings for this measure:

Non-coincident kW reduction with Interactive Effects = (kW of existing equipment - kW of replacement equipment) * (Demand Interactive Effects)

```
Coincident kW Reduction = Coincident Diversity Factor

× Noncoincident reduction with Demand Interactive Effects
```

I.6.7 Recommendations

Based on the size of this measure relative to other measures, we recommend on-site verifications and interviews to determine the energy savings. On-site data collection is recommended so that an accurate estimate of typical wattages of the new fixtures can be determined. Data collection (M&V) activities with lighting loggers should be conducted to

determine hours. However, due to the diverse nature of the locations where CFLs can be located, many different locations at a few sites with the same commercial or industrial end use (or SIC code) should be selected.

Secondary sources such as DEER and CEUS data may be valuable for determining pre retrofit and post retrofit wattages and operating hours.

Variables to be collected, their relative usefulness, and the method of data collection are defined in the following table. Underlined values denote the recommended approach given the projected overall efficacy of the collection method.

Table I-15: Collection Methods for CFL Lamps, 14 – 26 Watts

I.7.3 New Savings Estimates

See Lighting Logger Analysis.

I.7.4 Discussion of Relevant Variables

The energy savings resulting from the installation CFL fixtures is dependent on three main factors: operating hours, baseline demand, and installed demand. Of these factors, the operating hours tend to introduce the most uncertainty into the calculations. M&V studies tend to produce the best approximation of operating hours, although interview data can be helpful in estimating hours when more detailed data is not available.

I.7.5 Work Paper Assumptions

In addition to the above, below is a summary of significant assumptions:

- Savings are based on a 32-watt CFL with an electronic ballast consuming 0.031 kW, and
- The CFL replaces a 100-watt incandescent lamp.

Energy interactive effects are also defined per market sector and assume a cooling system efficiency and factor. The efficiency used and the source of these factors are not transparent.

I.7.6 Work Paper Equations

The following formula is used to estimate energy savings:

```
kWh Reduction with Interactive Effects = (kW of existing equipment - kW of replacement equipment)×(Annual operating hours) ×(Energy Interactive Effects)
```

The following formulas are used to estimate demand savings for this measure:

```
Non - coincident kW reduction with Interactive Effects = (kW \text{ of existing equipment}) \times (Demand Interactive Effects)
```

```
Coincident kW Reduction = Coincident Diversity Factor

× Non - coincident reduction with Demand Interactive Effects
```

I.7.7 Recommendations

Based on the size of this measure relative to other measures, we recommend on-site verifications and interviews to determine the energy savings. On-site data collection is recommended so that an accurate estimate of typical wattages of the new fixtures can be

determined. Data collection (M&V) activities with lighting loggers should be conducted to determine hours. However, due to the diverse nature of the locations where CFLs can be located, many different locations at a few sites with the same commercial or industrial end use (or SIC code) should be selected.

Secondary sources such as DEER and CEUS data may be valuable for determining pre retrofit and post retrofit wattages and operating hours.

Variables to be collected, their relative usefulness, and the method of data collection are defined in the following table. Underlined values denote the recommended approach given the projected overall efficacy of the collection method.

Table I-18: Collection Methods for CFL Lamps, >27 Watts

			Collection	Method		Use in	
Variable	Value	Secondary	Survey	On-Site	M&V	Equation	Source of Data

All Other	4,500	0.76	0.192	1,089

I.8.3 New Savings Estimates

See Lighting Logger Analysis.

I.8.4 Discussion of Relevant Variables

The energy savings resulting from the installation of high bay T5 lamps is dependent on three main factors: operating hours, baseline demand, and installed demand. Of these factors, the operating hours tend to introduce the most uncertainty into the calculations. M&V studies tend to produce the best approximation of operating hours, although interview data can be helpful in estimating hours when more detailed data is not available.

I.8.5 Work Paper Assumptions

In addition to the above, below is a summary of significant assumptions:

■ Savings are based on a 400-watt metal halide fixture consuming 0.458 kW replaced by a 4 lamp high output (HO) T-5 system consuming 234 watts

Energy interactive effects are also defined per market sector and assume a cooling system efficiency and factor. The efficiency used and the source of these factors are not transparent.

I.8.6 Work Paper Equations

The following formula is used to estimate energy savings:

The following formulas are used to estimate demand savings for this measure:

```
Non - coincident kW reduction with Interactive Effects = (kW \text{ of existing equipment}) \times (Demand Interactive Effects)
```

Coincident kW Reduction = Coincident Diversity Factor × Non - coincident reduction with Demand Interactive Effects

I.8.7 Recommendations

Based on the size of this measure relative to other measures, we recommend on-site verifications and interviews to determine the energy savings. On-site data collection is recommended so that an accurate estimate of typical wattages of the new fixtures can be determined. Data collection (M&V) activities with lighting loggers should be conducted to determine hours

Secondary sources such as DEER and CEUS data may be valuable for determining pre retrofit and post retrofit wattages and operating hours.

Variables to be collected, their relative usefulness, and the method of data collection are defined in the following table. Underlined values denote the recommended approach given the projected overall efficacy of the collection method.

Table I-21: Collection Methods for High Bay T5 Lamps

		Collection Method		Use in			
Variable	Value	Secondary	Survey	On-Site	M&V	Equation	Source of Data
Connected load incl. ballasts losses	Low	High (from manu-facturers)	Low	Low	N/A	Direct input (delta watts) to savings	Manufacturer documentation; Verifier observations
New wattage	High	Med	Med	High	N/A	Direct input (delta watts) to savings	Utility tracking system; Survey questions; Verifier observations; query site management/ maintenance staff
Replaced wattage	High	Low	Med	Med	N/A	Direct input (delta watts) to savings	Survey questions; Verifier observations; query site management/ maintenance staff; inspect other non- replaced lamps
Operating hours	High	Low	Med	Low	High	Direct input (delta hours) to savings	Survey questions; Verifier observations; query site management/ maintenance staff; light loggers
Failure Rate	Low	N/A	Med	Med	N/A	Impacts number of retrofits	Survey questions; Verifier observations; query site maintenance staff
Length of Time In Service	Low	Low	Med	Low	Low	Affects remaining life (savings)	Survey questions
Efficacy		Low	Low	Med	<u>High</u>		16

¹ Values given for various collection methods relate the relative accuracy of data collected for a given variable.

² Underlined values denote the recommended approach given the projected overall efficacy of the collection method.

³ M&V refers to primarily to light logger studies (including on site verification of installed wattage).

I.8.8 Results

The 16-year estimate of life may be a reliable estimate the true useful life. The cost per unit of \$250 per unit seems high but may be accurate, depending on assumptions used in discounting the initial investment.

See Lighting Logger Analysis for updated savings estimates and verification/engineering adjustment factors.

I.9 LED Exit Signs

I.9.1 Summary

■ Work Paper Savings Estimates: 351 kWh/yr; 0.042 kW

 Measure Cost: \$ 111 /new sign (the incremental costs is \$ 49.96 /unit based on discounted rates with lamp replacement)

Measure Life: 16 years

I.9.2 Prior Savings Estimates

The calculations assume that an exit sign fixture containing two 20-watt incandescent lamps is converted to an LED fixture. Total installed wattage drops from 0.040 kW to 0.004 kW. Fire code requires exit lights to operate for 8,760 hrs/yr. Therefore, demand reduction is $0.36 \text{ kW} \times 1.18 = 0.042 \text{ kW}$. Energy reduction is $0.036 \text{ kW} \times 8,760 \text{ hours per year} \times 1.114 = 351 \text{ kWh/year}$ (includes 11.4% average Energy Interactive Effects).

Table I-22: LED Exit Signs, Energy and Demand Interactive Effects

Market Sector	Energy Interactive Effects	Demand Interactive Effects
All Market Sectors	1.114	1.18

I.9.3 New Savings Estimates

The savings estimates were not modified as part of this evaluation.

I.9.4 Discussion of Relevant Variables

The energy savings resulting from the installation is dependent on two main factors: baseline demand and installed demand. Baseline demand is most relevant and interview data can be helpful in estimating the removed fixture demand.

I.9.5 Work Paper Assumptions

The energy interactive effects assume cooling system efficiency. The efficiency used is not detailed. The calculations assume that an exit sign fixture containing two 20-watt

incandescent lamps is converted to an LED fixture. Total installed wattage drops from 0.040 kW to 0.004 kW.

I.9.6 Work Paper Equations

The following formula is used to estimate energy savings:

```
kWh\ Reduction\ with\ Interactive\ Effects = (kW\ of\ existing\ equipment
-kW\ of\ replacement\ equipment) \times (Annual\ operating\ hours)
\times (Energy\ Interactive\ Effects)
```

The following formulas are used to estimate demand savings for this measure:

```
Noncoincident kW reduction with Interactive Effects = (kW \ of \ existing \ equipment - kW \ of \ replacement \ equipment) \times (Demand \ Interactive \ Effects)
```

Coincident kW Reduction = Coincident Diversity Factor

× Noncoincident reduction with Demand Interactive Effects

I.9.7 Recommendations

Based on the size of this measure relative to other measures, we recommend secondary data sources and phone surveys to determine the energy savings. On-site data collection, primarily collection of old and new wattages, is recommended so that an accurate estimate of typical wattages of the new fixtures (and old fixtures if possible) can be determined.

Secondary sources such as DEER and CEUS data may be valuable for determining pre retrofit and post retrofit wattages and operating hours.

Variables to be collected, their relative usefulness, and the method of data collection are defined in the following table. Underlined values denote the recommended approach given the projected overall efficacy of the collection method.

Table I-23: Collection Methods for LED Exit Signs

		C	Collection Method				
Variable	Value	Secondary	Survey	On- Site	M&V	Use in Equation	Source of Data
New wattage	Med	Low to Med	Med	High	N/A	Direct input (delta watts) to savings	Manufacturer documentation; Verifier observations; Survey questions
Replaced wattage	High	Med	Low	Med (if older fixtures exist)	N/A	Direct input (delta watts) to savings	Utility tracking system; Survey questions; Verifier observations; query site management/ maintenance staff; inspect other non-replaced lamps
Failure Rate	Low	N/A	Med	Low to Med	N/A	Factor in Net to Gross Calculations	Survey questions; Verifier observations; query site management/ maintenance staff
Length of Time In Service	Low	Low	Med	Low	N/A	Affects remaining life (savings)	Survey questions; Verifier observations; query site management/ maintenance staff
Efficacy		Low to Med	Med	Med	N/A		

¹ Values given for various collection methods relate the relative accuracy of data collected for a given variable.

I.9.8 Results

The 16-year estimate of life may underestimate the true useful life. The cost per unit of \$111 for a new fixture (installed) may be accurate, however, the \$49.96 life cycle costs will depend on assumptions used in discounting the initial investment.

Based on our analysis, no adjustments to the estimated work paper savings were necessary for this measure.

I.10 Occupancy Sensors – High Bay

I.10.1 Summary

Work Paper Savings Estimates: 789 kWh/yr; 0.381 kW

² Underlined values denote the recommended approach given the projected overall efficacy of the collection method.

Measure Cost: \$ 141 /unitMeasure Life: 8 years

I.10.2 Prior Savings Estimates

The occupancy sensor is assumed to control eight 4-foot 2-lamp fluorescent fixtures with 34 watt, T-12 lamps and energy saving magnetic ballasts (72 watts per fixture including ballast). The location that is modeled is a small conference room. Without the occupancy sensor, lights are assumed to burn 2,600 hours/year (50 hour/week for 52 weeks/year) and be manually switched off 15% of the time, for a total of 2,210 hours/year. It is assumed that the room is used only four hours/day (1,040 hours/year) and therefore the occupancy sensor turns off lights for 1,170 hours/year over the base case (45% reduction over manual switching).

Table I-24: Occupancy Sensors, Energy and Demand Interactive Effects

Market Sector	Energy Interactive Effects	Demand Interactive Effects
Office	1.17	1.25

I.10.3 New Savings Estimates

The savings estimates were not modified as part of this evaluation.

I.10.4 Discussion of Relevant Variables

The energy savings resulting from the installation is dependent on three main factors: post retrofit operating hours, baseline operating hours, and installed demand. M&V studies tend to produce the best approximation of operating hours, although interview data can be helpful in estimating hours when more detailed data is not available.

I.10.5 Work Paper Assumptions

In addition to the assumptions in the above section, energy interactive effects assume a cooling system efficiency and factor. The efficiency used and the source of these factors are not transparent.

I.10.6 Work Paper Equations

- Non-Coincident Demand Reduction
 - 0.305 kW when controls shut off equipment (0.576 kW x 0.53 reduction in hours)
- Coincident Demand Reduction
 - 0.381 kW (0.305 kW x 1.25 average office sector demand interactive effect)
- Energy Savings

Savings for all market sectors are 789 kWh per year, including 17% average office sector energy interactive effects.

I.10.7 Recommendations

Based on the size of this measure relative to other measures, we recommend on-site verifications and interviews to determine the energy savings. On-site data collection is recommended so that an accurate estimate of typical wattages of the controlled fixtures can be determined and data collection (M&V) activities with lighting loggers can be conducted to determine hours. There may be an opportunity to combine data collection activities with M&V activities for T-8 fixture conversion measures, as many customers who are installing occupancy sensors may also be converting the fixtures to T-8 with electronic ballasts.

However, it is expected that there are typical locations where this retrofit is appropriate; it is envisioned that a few typical locations should be selected at many different sites.

Spot measurements of wattages where lighting circuits can be isolated and verification of the types of lamps and ballasts can be used to confirm reported new wattages and power draw. Logging power use for selected circuits is also possible, if these circuits can be isolated. However, this is most applicable where dimming is employed, and is outside the scope of this measure.

Secondary sources such as DEER and CEUS data may be valuable for determining pre retrofit and post retrofit wattages and operating hours.

Variables to be collected, their relative usefulness, and the method of data collection are defined in the following table. Underlined values denote the recommended approach given the projected overall efficacy of the collection method.

Table I-25: Collection Methods for Occupancy Sensors

			Collection Method			Use in	
Variable	Value	Secondary	Survey	On-Site	M&V	Equation	Source of Data
Connected load including ballasts losses	High	High (with ballast loss from manu- facturers)	Low to Med	High (with ballast lamp information collected)	N/A	Direct input (watts) to savings	Manufacturer documentation; Verifier observations
Post retrofit operating hours	High	Low to Med	Low to Med	Low to Med	High	Direct input (delta hours) to savings	Utility tracking system; Survey questions; Verifier observations; query site management/ maintenance staff; light loggers
Pre retrofit operating hours	High	Low to Med	Med to High	Low to Med	N/A	Direct input (delta hours) to savings	Survey questions; Verifier observations; query site management/ maintenance staff; light loggers
Failure Rate of Sensor	Low	N/A	Med	Low to Med	N/A	Impacts number of retrofits	Survey questions; Verifier observations; query site management/ maintenance staff; light loggers
Length of Time In Service	Low	Low	Med	Low	N/A	Affects remaining life (savings)	Survey questions; Verifier observations; query site maintenance staff
Efficacy		Low	Low	Med	<u>High</u>		

¹ Values given for various collection methods relate the relative accuracy of data collected for a given variable.

I.10.8 Results

The eight-year estimate of life may reliably estimate the true useful life. The cost per unit of \$141 per unit seems appropriate for this application. Due to complexities of collecting preand post-operating hours, no adjustments to the estimated work paper savings were made for this measure.

² M&V refers to primarily to light logger studies (including on site verification of installed wattage).

I.11 Occupancy Sensors - Ceiling

The summary, description, and results are identical to high bay occupancy sensors discussed above.

I.12 Occupancy Sensors – Wallbox

I.12.1 Summary

■ Work Paper Savings Estimates: 266 kWh/yr; 0.111 kW

Measure Cost: \$ 56 /unitMeasure Life: 8 years

I.12.2 Prior Savings Estimates

For this calculation, the occupancy sensor is assumed to control three 4-foot 2-lamp fluorescent fixtures with 34 watt, T-12 lamps and energy saving magnetic ballasts (72 watts per fixture including ballast). The location that is modeled is a private office space. Without the occupancy sensor, lights are assumed to burn during building hours of operation (60 hours/week for 50 weeks/year) and be manually switched off 15% of the time, for a total of 2,550 hours/year. It is assumed that the office occupant spends six hours per day in the office for 50 weeks/yr, (1,500 hours/year) so that the occupancy sensor turns off lights for 1,050 hours/year (41% reduction over manual switching).

Table I-26: Occupancy Sensors – Wallbox, Energy and Demand Interactive Effects

Market Sector	Energy Interactive Effects	Demand Interactive Effects
Office	1.17	1.25

I.12.3 New Savings Estimates

The savings estimates were not modified as part of this evaluation.

I.12.4 Discussion of Relevant Variables

The energy savings resulting from the installation is dependent on three main factors: baseline operating hours, baseline operating hours, and installed demand. M&V studies tend to produce the best approximation of operating hours, although interview data can be helpful in estimating hours when more detailed data is not available.

I.12.5 Work Paper Assumptions

The above sections contain the significant assumptions.

Energy interactive effects assume a cooling system efficiency and factor. The efficiency used and the source of these factors are not transparent.

I.12.6 Work Paper Equations

- Non-Coincident Demand Reduction
 - 0.089 kW when controls shut off equipment (0.216 kW x 0.41 reduction in hours).
- Coincident Demand Reduction
 - 0.111 kW (0.089 kW x 1.25 average office sector demand interactive effects).
- Energy Savings
 - Savings for all market sectors are 266 kWh per year, including 17% average office sector energy interactive effects.

I.12.7 Recommendations

Based on the size of this measure relative to other measures, we recommend on-site verifications and interviews to determine the energy savings. On-site data collection is recommended so that an accurate estimate of typical wattages of the controlled fixtures can be determined and data collection (M&V) activities with lighting loggers can be conducted to determine hours. There may be an opportunity to combine data collection activities with M&V activities for T-8 fixture conversion measures, as many customers who are installing occupancy sensors may also be converting the fixtures to T-8 with electronic ballasts.

However, it is expected that there are typical locations where this retrofit is appropriate; it is envisioned that a few typical locations should be selected at many different sites.

Spot measurements of wattages where lighting circuits can be isolated and verification of the types of lamps and ballasts can be used to confirm reported new wattages and power draw. Logging power use for selected circuits is also possible, if these circuits can be isolated. However, this is most applicable where dimming is employed, and is outside the scope of this measure.

Secondary sources such as DEER and CEUS data may be valuable for determining pre retrofit and post retrofit wattages and operating hours.

Variables to be collected, their relative usefulness, and the method of data collection are defined in the following table. Underlined values denote the recommended approach given the projected overall efficacy of the collection method.

Table I-27: Collection Methods for Occupancy Sensors – Wallbox

		C	ollection I	Method		Use in	
Variable	Value	Secondary	Survey	On-Site	M&V	Equation	Source of Data
Connected load incl. ballasts losses	High	High (with ballast loss from manufacturers)	Low to Med	High (with ballast lamp information collected)	N/A	Direct input (watts) to savings	Manufacturer documentation; Verifier observations
Post retrofit operating hours	High	Low to Med	Low to Med	Low to Med	High	Direct input (delta hours) to savings	Utility tracking system; Survey questions; Verifier observations; query site management/ maintenance staff; light loggers
Pre retrofit operating hours	High	Low to Med	Med to High	Low to Med	N/A	Direct input (delta hours) to savings	Survey questions; Verifier observations; query site management/ maintenance staff; light loggers
Failure Rate of Sensor	Low	N/A	Med	Low to Med	N/A	Impacts number of retrofits	Survey questions; Verifier observations; query site management/ maintenance staff; light loggers
Length of Time In Service	Low	Low	Med	Low	N/A	Affects remaining life (savings)	Survey questions; Verifier observations; query site maintenance staff
Efficacy		Low	Low	Med	<u>High</u>		

¹ Values given for various collection methods relate the relative accuracy of data collected for a given variable.

I.12.8 Results

The 8-year estimate of life may reliably estimate the true useful life. The cost per unit of \$ 56 per unit seems appropriate for this application. Due to the complexities of collecting pre-

² Underlined values denote the recommended approach given the projected overall efficacy of the collection method.

³ M&V refers to primarily to light logger studies (including on site verification of installed wattage).

and post-operating hour information, no adjustments to the estimated work paper savings were made for this measure.

I.13 T8 Electronic Ballasts

I.13.1 Summary

■ Work Paper Savings Estimates: 22 to 60 kWh/yr; 0.005 to 0.009 kW per lamp

New Estimated Savings: See Lighting Logger Analysis

■ Engineering Adjustment Factor: See Lighting Logger Analysis

Measure Cost: \$ 15/ lampMeasure Life: 16 years

I.13.2 Prior Savings Estimates

The work paper indicates the savings estimate was based on usage and formulae described below, with a non-coincident demand reduction of 0.09 kW/lamp.

Table I-28: T8 Electronic Ballasts, Energy and Demand Interactive Effects by Market Sector

Market Sector	Energy Interactive Effects	Demand Interactive Effects
Office	1.17	1.25
Retail	1.11	1.19

The calculations are for replacement of lamps and ballast(s) in a 4-foot fluorescent fixture. The T-12 lamps and energy saving magnetic ballast(s) are replaced with an electronic ballast and 32 watt, T-8 lamps. Most 4-foot fixtures are either 2-lamp or 3-lamp fixtures. Savings and cost data are the average of the 2-lamp and 3-lamp data.

Table I-30: T8 Electronic Ballasts, Savings Per Lamp by Fixture

Average				0.009

I.13.3 New Savings Estimates

See Lighting Logger Analysis

I.13.4 Discussion of Relevant Variables

The energy savings resulting from the installation is dependent on three main factors: operating hours, baseline demand, and installed demand. M&V studies tend to produce the

best approximation of operating hours, although interview data can be helpful in estimating hours when more detailed data is not available.

I.13.5 Work Paper Assumptions

In addition to the above, energy interactive effects are also defined per market sector and assume a cooling system efficiency and factor. The efficiency used and the source of these factors are not transparent.

I.13.6 Work Paper Equations

The following formula is used to estimate energy savings:

The following formulas are used to estimate demand savings for this measure:

Noncoincident kW reduction with Interactive $Effects = (kW \text{ of existing equipment} - kW \text{ of replacement equipment}) \times (Demand Interactive Effects)$

Coincident kW Reduction = Coincident Diversity Factor

× Noncoincident reduction with Demand Interactive Effects

- Non-Coincident Demand Savings
 - 0.009 kW per lamp
- Coincident Demand Reduction
 - Coincident demand reduction varies by sector because of differences in usage patterns. All values are shown in the table on the following page and are per lamp.
- Energy Savings
 - The basic equation is hours times kW reduction. Energy savings vary by sector because of differences in operating hours. Annual energy savings adjusted for sector-specific interactive effects are given in the table below and are per lamp.

I.13.7 Recommendations

Based on the size of this measure relative to other measures, we recommend on-site verifications and interviews to determine the energy savings. On-site data collection is recommended so that an accurate estimate of typical wattages of the new fixtures can be determined. Data collection (M&V) activities with lighting loggers should be conducted to

determine hours. However, due to the diverse nature of the locations where CFLs can be located, many different locations at a few sites with the same commercial or industrial end use (or SIC code) should be selected.

Secondary sources such as DEER and CEUS data may be valuable for determining pre retrofit and post retrofit wattages and operating hours.

Variables to be collected, their relative usefulness, and the method of data collection are defined in the following table. Underlined values denote the recommended approach given the projected overall efficacy of the collection method.

Table I-31: Collection Methods for T8 Electronic Ballasts

		Collection Method				Use in	
Variable	Value	Secondary	Survey	On-Site	M&V	Equation	Source of Data
Connected load including ballasts losses	Low	High (from manu- facturers)	Low	Low	N/A	Direct input (delta watts) to savings	Manufacturer documentation; Verifier observations

Efficacy		Low	Low	Med	<u>High</u>		llected for a given

¹ Values given for various collection methods relate the relative accuracy of data collected for a given variable.

² Underlined values denote the recommended approach given the projected overall efficacy of the collection method.

³ M&V refers to primarily to light logger studies (including on site verification of installed wattage).

I.13.8 Results

The 16-year estimate of life may accurately estimate the true useful life. The cost per unit of \$15 /lamp may be somewhat low given current markets, depending on the fixture locations and quantities retrofit.

See Lighting Logger Analysis for updated savings estimates and verification/engineering adjustment factors.

I.14 Delamp (4-Foot Lamp Only)

I.14.1 Summary

- Work Paper Savings Estimates: 106 to 289 kWh/yr; 0.022 to 0.045 kW per fixture
- New Estimated Savings: See Lighting Logger Analysis
- Engineering Adjustment Factor: See Lighting Logger Analysis
- Measure Cost: \$ 19 /unit (based on one reflector discounted rates)
- Measure Life: 16 years (average)

I.14.2 Prior Savings Estimates

The work paper indicates the savings estimate was based on usage and formulae shown below, with a non-coincident demand reduction of 0.043 kW.

Table I-32: Delamping (4-ft lamp only), Energy and Demand Interactive Effects by Market Sector

Market Sector	Energy Interactive Effects	Demand Interactive Effects

All Other	4,500	0.76	0.037	209

I.14.3 New Savings Estimates

See Lighting Logger Analysis.

I.14.4 Discussion of Relevant Variables

The energy savings resulting from the installation is dependent on three main factors: operating hours, baseline demand, and installed demand. Of these factors, the operating hours tend to introduce the most uncertainty into the calculations. M&V studies tend to produce the best approximation of operating hours, although interview data can be helpful in estimating hours when more detailed data is not available. However, greater uncertainty may be introduced if the conversion involves the removal of two lamps.

I.14.5 Work Paper Assumptions

Savings are based on a T12 34 watt lamp and a ballast being removed, reducing wattage form 115 watts to 72 watts. Energy interactive effects are also defined per market sector and assume a cooling system efficiency and factor. The efficiency used and the source of these factors are not transparent.

I.14.6 Work Paper Equations

The following formula is used to estimate energy savings:

 $kWh\ Reduction\ with\ Interactive\ Effects = (kW\ of\ existing\ equipment$ $-kW\ of\ replacement\ equipment) \times (Annual\ operating\ hours)$ $\times (Energy\ Interactive\ Effects)$

The following formulas are used to estimate demand savings for this measure:

Noncoincident kW reduction with Interactive Effects = $(kW \text{ of existing equipment}) \times (Demand Interactive Effects)$

Coincident kW Reduction = Coincident Diversity Factor

× Noncoincident reduction with Demand Interactive Effects

I.14.7 Recommendations

Based on the size of this measure relative to other measures, we recommend on-site verifications and interviews to determine the energy savings. On-site data collection is recommended so that an accurate estimate of typical wattages of the new fixtures can be determined. Data collection (M&V) activities with lighting loggers should be conducted to determine hours.

It is likely that all delamping measures can be aggregated with T-8 fixture conversion measures for a lighting logger study, as most customers who are delamping fixtures will also be converting the fixtures to T-8 with electronic ballasts.

Secondary sources such as DEER and CEUS data may be valuable for determining pre retrofit and post retrofit wattages and operating hours.

Variables to be collected, their relative usefulness, and the method of data collection are defined in the following table. Underlined values denote the recommended approach given the projected overall efficacy of the collection method.

Table I-34: Collection Methods for Delamping (4-ft lamp only)

		Co	Collection Method				
Variable	Value	Secondary	Survey	On- Site	M&V	Use in Equation	Source of Data
New wattage	High	Low	Low	High	High	Direct input (delta watts) to savings	Survey questions; Verifier observations; query site management/ maintenance staff; inspect other non- replaced lamps; power measurement
Replaced wattage	High	Low	Med	Med	N/A	Direct input (delta watts) to savings	Survey questions; Verifier observations; query site management/ maintenance staff; inspect other non- replaced lamps
Operating hours	High	Low	Med	Med	High	Direct input (hours) to savings	Survey questions; Verifier observations; query site management/ maintenance staff; light loggers
Efficacy		Low	Med	Med	<u>High</u>		

¹ Values given for various collection methods relate the relative accuracy of data collected for a given variable.

I.14.8 Results

The 16-year estimate of life may accurately state the true useful life. The cost per unit of \$19 per unit may be low if no other retrofit is being performed on the fixture.

See Lighting Logger Analysis for updated savings estimates and verification/engineering adjustment factors.

I.15 Door Gaskets

I.15.1 Summary

■ Work Paper Savings Estimates: 2,091 kWh/year/gasket; 0.239 kW/gasket

New Estimated Savings: 2,300 kWh/year/gasket; 0.241 kW/gasket

■ Engineering Adjustment Factor: 110%

² Underlined values denote the recommended approach given the projected overall efficacy of the collection method

³ M&V refers to primarily to light logger studies (including on site verification of installed wattage).

Measure Cost: \$4.00/linear foot (lf)

■ Measure Life: 4 years

Note: The gasket savings are per gasket of 20 linear feet (If or ln. ft.).

I.15.2 Prior Savings Estimates

The savings estimates are based on engineering savings calculations using ASHRAE calculation methods. The calculation methodology is consistent and well documented.

I.15.3 New Savings Estimates

No revision to the calculations is necessary based on the available information. Savings are refined by better determination of input variables.

I.15.4 Discussion of Relevant Variables

Relevant variables are the areas, temperature difference, and hours the door is not fully closed. The door open hours are the most important variable to accurately quantify. The estimated hours the doors are open, the estimated ratio of cooler vs. freezer installations, and the age/condition of the strip curtains may be able to be determined through participant surveys. All variables could be better characterized though observations and interviews possible during site visits

I.15.5 Work Paper Assumptions

Below is a summary of significant assumptions affecting the savings estimates contained in the work paper:

- Walk-in doors closed 5,750 hours per year (8,760 3,010 hours left open or ajar)
- Door opening is 3' x 7'
- Weak gaskets on coolers and freezers allow loss of 3% of the open door heat loss
- Eighty percent of installations are coolers, 20% are freezers
- Exterior temperature is 70° F and 60% RH
- Refrigerator temperature is 40°F, freezer temperature is 0°F
- Cooler and freezer performance factor is 1.6 kW/ton and 2.4 kW/ton, respectively

I.15.6 Work Paper Equation

The following formula from the ASHRAE Refrigeration Handbook 1990 was used to estimate the heat flow through the door in order to determine the energy savings from installation of gaskets:

$$q_t = 3,790 \cdot WH^{1.5} (Q/A)(1/R)D_tD_f$$

Where

```
average heat gain in a period (Btu/h)
q_t
W
              door width = 3
Н
              door height = 7
        =
Q/A
               sensible heat load of infiltration per sq. ft. of doorway (ASHRAE, 2002,
              Fig. 3, 12.4)
R
              sensible heat ratio of the infiltration air heat gain (ASHRAE, 2002, Table
              7, 12.5)
              door open time factor
D_{t}
              door flow factor = 0.80 unmodified flow factor x 0.03 loss
D_{\scriptscriptstyle f}
```

The ASHRAE Refrigeration Handbook 2002 (Chapter 12) has identical calculations.

I.15.7 Recommendations

Itron recommends that the assumptions used in the calculations be reviewed. The savings estimates for the current 2004 work papers are based on engineering calculations and market assumptions that are approximately 10 years old. The assumption that old door gaskets allow 3% of open door loss is not detailed or explained. In addition, there is an implicit assumption that a new door gasket will eliminate all open door losses throughout the lifetime of the gasket.

Based on an evaluation of the variables needed for an accurate estimate of savings and the resources needed to obtain these variables, telephone surveys may be the best use of resources to obtain the most relevant data. On site visits will also increase the accuracy of savings estimates from a low to a medium level.

The phone surveys might also be conducted to inquire as to the condition of the old gaskets prior removal, the condition of the installed gaskets mid-way through their useful life and to verify reported time of utilization (when the doors are closed).

No direct measurement and verification is recommended due to the overall contribution to the portfolio. Direct measurement would apply only to door open time.

There may be only limited data from secondary sources such as CEUS or DEER which are thought to have any applicable information for this measure. The ratio of cooler to freezer walk-in boxes may be able to be determined from the population data.

Exterior temperatures, if the location of the box is outdoors, may be determined from census data and tracked by ZIP codes. The number of exterior locations for walk in boxes is thought to be minimal (less than 20%) and could be determined in the telephone surveys.

Variables to be considered are summarized in the following table.

Table I-35: Collection Methods for Door Gaskets

			Collection M	Iethod		Use in	
Variable	Value	Secondary	Survey	On-Site	M&V	Equation	Source of Data
Unit type - cooler/freezer	High	Low	High	High	High	Determines Q/A and R in equation	Survey Questions; Verifier observations
Utilization (door open time)	High	n/a	Med	Med	High	Directly proportiona l to savings	Survey Questions; Verifier observations
Condition of old gaskets	Med	n/a	Low	Low	High	Percent effectivene ss	Survey Questions; Verifier observations
Door Dimensions	Med	n/a	Med	High	High	Directly proportiona l to savings	Survey Questions; Verifier observations
Interior temperature	Low	Low	High	High	High	Determines Q/A and R in equation	Survey Questions; Verifier observations
Exterior temperature	Low	Med	Med	Med	High	Determines Q/A and R in equation	Survey Questions; Verifier observations
Total Accuracy		Low	Med	<u>Med</u>	High		

I.15.8 Results

The engineering realization rate was 110 % and was adjusted according to the average of the hours of daily operation in which the doors were closed (which were found to be higher than in the work papers). Other variables for which the engineering realization rate were adjusted

are the dimensions of the door and the type of refrigerated space (cooler, freezer, or uncooled).

Table I-36: Summary – Gaskets

# of Sites Used in Engineering Analysis	10
Total Rebated (ln. ft.)	955
Total Verified (ln. ft.)	908
WP # hrs door closed	6,114
# hrs door closed	8,264
WP Savings/door (kWh/yr)	1,450
Savings/door (kWh/yr)	1,596
Engineering Realization Rate	89%

The 4-year estimate of life may underestimate the true useful life. The cost of \$4 per lf (installed) may be accurate, however, based on previous research showing costs of \$80 per 20-foot length of gasket.

I.16 Efficient Evaporator Fan Motors – Electronically Commutated Motor

I.16.1 Summary

■ Work Paper Savings Estimates: 673 kWh/year; 0.086 kW non-coincident peak

■ New Estimated Savings: 673 kWh/year; 0.086 kW non-coincident peak (no data points available to modify estimates)

Engineering Adjustment Factor: 1.00

Measure Cost: \$161/motorMeasure Life: 16 years

Note: The savings presented in the work paper summary and above are for a motor covering four linear feet of refrigerated case.

I.16.2 Prior Savings Estimates

The baseline for this measure consists of a standard efficiency shaded pole evaporative fan motor on refrigerated display cases or fan coil systems of walk-in units. The measure consists of replacing the motor with a more efficient electronically commutated motor. The savings estimates are based on the change in the demand of the baseline and installed motor along with associated interactive compressor savings due to the reduced heat load. The energy savings are given per length of the cooler in feet with the assumption of two motors

per eight foot case. The estimates of savings were presented for each motor and used estimates for operating hours, for the energy efficiency ratio (EER) and for the kW/ft savings. The savings are reasonable but there are minor discrepancies in the hours used and in the kW and kWh savings.

I.16.3 New Savings Estimates

No additional information on the actual sizes of motors and types of refrigerated units was available, as no sites could be verified or evaluated. The savings estimate in the work paper was unchanged.

I.16.4 Discussion of Relevant Variables

Relevant variables are the size of the motor controlled, the percent of time energized, and the energy efficiency ratio used. Of particular interest, the savings of a motor load reduction of 0.015 kW/ft in most significant, as this affects both direct motor savings and cooling savings. (Note that 0.016 kW/ft was used for cooling savings, a minor inconsistency). The use of 8,760 hours per year for continuous fan operation should be verified and applied to the cooling savings as well (instead of the 5,700 equivalent full load hours) if this is justified.

I.16.5 Work Paper Assumptions

The work paper assumption is that the savings in kW/ft is valid, that the evaporator fans run continuously, and that the EER of 8.51 Btu/hr/watts is representative.

I.16.6 Work Paper Equation

The equations employed are as follows:

```
kW saved = kW/ft motor savings + kW/ft x 3,413 Btuh/kW/EER/100 w/kW

kWh saved = kW/ft motor savings x 8,760 hrs/yr +

kW/ft x 3,413 Btuh/kW/EER/100 w/kW x 5,700 EFLH/yr
```

I.16.7 Recommendations

Based on the size of this measure relative to other measures, we recommend that these savings figures be verified and the work paper be modified. Savings should be presented per linear foot or more fully noted to avoid confusion.

Table I-37: Collection Methods for Efficient Evaporative Fan Motors

			Collection	Method		Use in	Source of
Variable	Value	Secondary	Survey	On-Site	M&V	Equation	Data
Use	Low						
Motor Size	High	Low	Low	High	N/A	Will influence kW/ft savings	Survey Questions; Verifier observations
EER	High	Low	Med	High	NA	Direct input	Survey Questions; Verifier observations
Hrs/yr	Med	Low	Low	Med	High	Direct input	Survey Questions; Verifier observations
Efficacy		Low	Low	Med	High		

I.17 Strip Curtains

I.17.1 Summary

■ Work Paper Savings Estimates: 465 kWh/year/sq. ft., 0.0531 kW/sq. ft. (coincident)

New Estimated Savings: 150 kWh/year/sq. ft., 0.0171kW/sq. ft. (coincident)

■ Engineering Adjustment Factor: 0.32

Measure Cost: \$3.05/sq. ft.Measure Life: 4 years

I.17.2 Prior Savings Estimates

The savings estimates contained in the work paper are based on the ASHRAE 1994 Refrigeration Handbook and modified based on 1996 M&E studies. While the methodology appears appropriate and the savings may be realistic, current market assumptions should be tested.

I.17.3 New Savings Estimates

The savings estimates are based on engineering savings calculations using identical ASHRAE calculation methods. The calculation methodology is consistent and well documented. No revision to the calculations is necessary based on the available information. However, the number of hours the strip curtains are effective (i.e., door open time) and the

percentage of coolers and freezers found in the field, significantly changed the savings estimates, as noted in the above summary.

I.17.4 Discussion of Relevant Variables

The estimated hours the doors are open, the estimated ratio of cooler vs. freezer installations, and the age/condition of the strip curtains are important and should be determined through participant surveys. All variables could be better characterized though observations and interviews possible during site visits.

I.17.5 Work Paper Assumptions

Below is a summary of significant assumptions:

- The door is 3' x 7'
- Strip curtains are 80% effective in reducing infiltration
- Walk-in doors are open 3 hours a day, 7 days a week
- Eighty percent of installations are coolers, 20% are freezers
- Exterior temperature is 70°F and 60% R.H.
- Refrigerator temperature is 40°F, Freezer Temperature is 0°F

I.17.6 Work Paper Equation

The following formula from the ASHRAE Refrigeration Handbook was used to estimate the heat flow through the door in order to determine the energy savings from installation of strip curtains:

$$qt = 3,790 \times W \times H\Lambda 1.5 \times (Q/A) \times (1/R) \times Dt \times Df \times (1-E)$$

where:

qt = average heat gain in a period (Btu/h)

W = door width H = door height

Q/A = sensible heat load of infiltration per square foot of doorway

R = sensible heat ratio of the infiltration air heat gain

 D_t = door open time factor

 D_f = door flow factor

E = effectiveness of doorway protective device (0 = unobstructed doorway)

The cooler impact is initially calculated with the assumption that the door

is left open for an entire hour.

Dt = 1.0

Df = 0.8 flow factor

E = 80%

Q/A = 0.16 tons/sq.ft.

$$R = 0.59$$

I.17.7 Recommendations

Based on the size of this measure relative to other measures, we recommend on-site verifications and interviews to determine the energy savings. On-site data collection is recommended so that an accurate estimate of the variables listed in the following table. Data collection (M&V) activities with door closure loggers may be conducted.

A small number of on-site visits (with interviews and on-site observations) could be conducted to verify the condition of curtains toward the mid-span of their useful life and to verify, as possible, reported time of utilization (when the doors are open). However, these visits would only significantly aid in the assessment of curtain condition. The factor E would be affected; this value is believed to be consistently high (a value of 0.8, correlating to 80% effectiveness, was used in the work paper). Thus, the impact of this variable is low and site visits would have limited effect. Accuracy would be expected to be slightly higher.

Direct measurement would apply to door dimensions. Open time would be determined through interviews and observation.

Exterior temperatures, if the location of the box is located outdoors, may be determined from census data and tracked by ZIP codes. The number of exterior locations for walk in boxes is thought to be minimal (less than 20%) and could be determined in the telephone surveys.

Table I-38: Collection Methods for Strip Curtains

			Collection Mo	ethod			Possible
Variable	Value	Secondary	Survey	On-Site	M&V	Use in Equation	Sources Of Data
Service temperature (cooler, freezer, or indoor temp)	Med	Low to Med	Med to High (quantity may be uncertain)	High	N/A	Direct input (may affect Q/A and 1/R by driving heat flow)	Survey Questions; Verifier observations
Temperature where cooler/freezer is located	Med	Low to Med	Med (quantity may be uncertain)	High	N/A	Direct input (directly affects Q/A and 1/R)	Survey Questions; Verifier observations
Indoor/outdoor location	High	Low	Med (quantity may be uncertain)	High	N/A	Direct input (directly affects Q/A and 1/R)	Survey Questions; Verifier observations
Condition	High	Low	Low	Med	N/A	Direct input (directly affects E)	Survey Questions; Verifier observations
Traffic (high/low/med)	Low	N/A	Med	Med	High	Verifies door open time factor D _t	Survey Questions; Verifier observations; Door Closure Switch
% of time walk- in door open	High	Low	Low to Med	Med	High	Direct input for (directly affects Q/A and 1/R)	Survey Questions; Verifier observations; Door closure switch or temperature sensor or light sensor
Door height	High	Low to Med	Med	High	N/A	H raised to the 1.5 power (H^1.5) is directly proportional to heat gain	Survey Questions; Verifier observations

Door width Efficacy	High	Med Low	Med Low	High Med	N/A High	proportional to heat gain	Verifier observations
		Low to			W is directly	Survey Questions;	

Note: M&V refers to primarily to door closure switch studies - % of on time may be able to be collected based on light sensors in walk in box or door closure switches (as a proxy)

I.17.8 Results

The engineering realization rate was 32% and was determined by: 1) the ratio of the hourly estimates confirmed in the field of the hours of door open time, 2) the ratio of coolers to freezers, and 3) the dimensions of the walk in doors. The strip curtains found in the field were in good to fair condition. Based on these findings, the four-year estimate of life may approximate the true useful life. The cost per square foot estimate appears reasonable.

I.18 Hot Water Boilers

I.18.1 Summary

■ Work Paper Savings Estimates: 2,937 therms/yr

New Estimated Savings: 4,231 therms/yr
 Engineering Adjustment Factor: 1.43

Measure Cost: \$1,671/unit (incremental)

Measure Life: 20 years

I.18.2 Prior Savings Estimates

The method of calculating the savings estimates are not explicit. However, with an increase of efficiency of 8% and an annual use of 8,760 hours with a loading factor of 30% overall, the savings are realistic for the average size of boiler reflected in the summary.

I.18.3 New Savings Estimates

Additional information collected on the actual sizes of boilers was responsible for the majority of the increase from the work paper estimated savings. As presented in the results section below, the average boiler size was 1,557 MBH, verses 976MBH.

I.18.4 Discussion of Relevant Variables

Besides boiler size, other relevant variables are the increase in efficiency, hours of use and loading factor. These are described in following sections.

I.18.5 Work Paper Assumptions

Below is a summary of significant assumptions affecting the savings estimates contained in the work paper:

- Data based on average equipment characteristics of SoCalGas customer participants for 2001 Express Efficiency Programs (expected to impact average rated input of 976 MBH).
- Average efficiency is greater than 82% (as required by program terms and conditions.
- Applications are primarily commercial and institutional (offices, restaurants, retail, schools, colleges, hotels, motels, and recreational facilities).

Note that terms and conditions require a minimum size of 75 MBH. Pool and spa usages are excluded

The work paper savings are consistent with an increase of efficiency of 8% and an annual use of 8,760 hours with a loading factor of 30% overall, but are not explicitly defined.

I.18.6 Work Paper Equation

The equation employed in the work paper was not defined.

However, for the new savings estimates, the following formula was used:

 $MBH\ saved = MBH\ boiler\ average \times 10\%\ efficiency\ increase \times hours\ /\ yr \times loading\ factor$

where:

annual use = actual use from field visits = 560 to 8,760 hours loading factor = 35% to 100%

Alternately, an estimate of MBH savings can be:

$$(MBH/eff_{old} - MBH / eff_{new})$$

Use of this factor yields slightly higher savings.

I.18.7 Recommendations

Itron recommends that the boiler size and underlying use (i.e., type of facility) be determined to formulate a valid savings estimate.

The 2001 work paper referenced a boiler size of 150 MBH, an office building with 1200 people, and an increase in efficiency from 80.4% to 82.5% AFUE (possible with intermittent ignition and vent dampers) to derive a typical energy savings of 63 therms per year.

The 2004/2005 work paper used an average size of 976 MBH based on PY 2001 installations in SoCalGas territory.

Although not explicit in the calculations, if efficiency is increased from 80.4% to an average of 88% (through the use of condensing technologies referred to as heat recovery from stack gases in the 2004/2005 work paper), and assuming a load factor of 30%, annual energy use savings are similar to those contained in that work paper (2,755 vs. 2,937 therms).

Most energy use is thought to occur where occupancy durations are high, namely commercial apartment buildings and hotels/motels. Load factor data for these units was not able to be obtained. However, for 50 unit apartment buildings, ASHRAE notes a maximum hot water demand of 10 gallons per hour (gph) per unit, with an average daily usage of 40 gallons/unit per day. For this application, the unit could be sized at 8 gph (to account for typical storage capacity). Thus, the boiler would typically be energized for 5 hours in the 24-hour period, for this application. This equates to a load factor of 21% (increasing to 24% if an efficiency of 88% is used and 26% if a distribution efficiency of 90% is also applied).

The load factor will vary based upon both the application and the size of the storage capacity (which will vary cross types of facilities and within facility types). However, the load factor might be expected to be between 20% and 40% across facility types.

The boiler size may be expected to vary between 300 MBH (300,000 Btuh) and 2,000 MBH at the upper end (e.g., for hospitals using a 50 hp boiler for hot water).

The size and the efficiency of the boilers are the most important variables to determine. If equipment just above the minimum efficiency for program eligibility is used, then energy savings will be minimal. However, energy savings could be more than forecast if the majority of equipment installed is condensing (i.e., utilizing heat recovery) and has efficiencies higher than 90%. All variables could be better characterized though observations and interviews possible during site visits.

Variables to be considered are summarized in the following table.

Table I-40: Collection Methods for Hot Water Boilers

			Collection			Possible	
Variable	Value	Secondary	Phone Survey	Site Visit	M&V	Use	Sources Of Data
Facility Type	Medium	High	High	High	NA	Helps validate LF in equation	Survey Questions; Verifier observations
Load Factor (LF)	High	Low	Low	Medium	High	Directly proportional to savings	Survey Questions; Verifier observations
eff _{old}	Medium	Low	Low	Medium	NA	Determines MBH saved in equation	Survey Questions; Verifier observations
eff _{new}	High	Low	Low	High	High	Determines MBH saved in equation	Survey Questions; Verifier observations
hours/yr	High	Low	High	High	High	Directly proportional to savings	Survey Questions; Verifier observations
Total Accuracy		Low	Medium	<u>High</u>	High		

Based on an evaluation of the variables needed for an accurate estimate of savings and the resources needed to obtain these variables, telephone surveys and on site surveys are the best use of resources to obtain the most relevant data. This would increase the accuracy of savings estimates from a low to a high level.

Specifically, the efficiency of the new boiler, (including the type – condensing verses non-condensing - and the make/model) should be determined. The number of hours per year should also be identified. In the interview, the type of facility and use of hot water can be confirmed.

No direct measurement is recommended due to the overall contribution to the total energy savings (the aggregate portfolio of measures). Direct measurement would yield only an estimate of the load factor or the new equipment efficiency for a few of the participants and this would not be necessarily representative of the entire population.

I.18.8 Results

Savings are greater due to the larger size of installed boilers in the program. Further, attempts were made to accurately determine the number of hours and the load factor was estimated according to the usage type. Unfortunately, the efficiency of the removed units could not be accurately assessed and an efficiency increase of 10% was assumed for all boilers.

There are significant opportunities to better assess these variables with a larger sample for better energy savings determination

The listed boiler life appears reasonable; however, the incremental cost may be low for this size of boiler. No details are provided for the cost calculation.

I.19 H-Axis Clothes Washers

I.19.1 Summary

■ Work Paper Savings Estimates: 148.9 therms/year

New Estimated Savings: 197.6

Engineering Adjustment Factor: 1.33Measure Cost: \$407 (incremental)

■ Measure Life: 10 years

I.19.2 Prior Savings Estimates

The work paper indicates the savings estimate was based on 6 cycles a day, 365 days per year, and a savings of 0.68 therms per cycle, based on documentation for the San Diego County Water Authority. It is indicated that there are both water heating and gas dryer savings.

These savings are realistic but may be slightly high. A May 2000 FEMP study (DOE/EE-0218) *Assessment of High-Performance, Family-Sized Commercial Clothes Washers*, showed gas savings of 81 therms/year based on 6.4 cycles/day. This data was based on monitoring results from a military facility where vertical-axis baseline machines were replaced with high-performance horizontal-axis machines.

Other calculations yield similar results. Commercial clothes washers meeting CEE Tier 1, 2, 3a, or 3b standards qualify for express efficiency incentives. Using the corresponding federal clothes washer energy rating factor, the Modified Energy Factor (MEF), at 6 cycles per day, gas savings will range from 78 therms/year for Tier 1 washers to 98 therms/year from Tier 3a and 3b washers.

I.19.3 New Savings Estimates

Savings were adjusted based on cycles per day, which increased from 6 cycles to 8 cycles.

I.19.4 Discussion of Relevant Variables

Relevant variables are the use of hot water and the cycles per day. The size of the washer will also have some impact; there is however, no reference to size in the work paper.

I.19.5 Work Paper Assumptions

Significant assumptions are the 0.068 therms per cycle claimed as savings.

I.19.6 Work Paper Equation

The equation employed is:

6 cycles per day × 365 days per year × 0.68 terms per cycle = 148.92 therms per year saved

I.19.7 Recommendations

Based on the size of this measure relative to other measures, we recommend a combination of telephone surveys and site visits for verification.

Table I-42: Collection Methods for H-Axis Clothes Washers

		(Collection N	Method		Use in	Source of
Variable	Value	Secondary	Survey	On-Site	M&V	Equation	Data
Type of Facility	Low	Med	High	High	NA	Indirect for validation	Survey Questions; Verifier observations
# of Cycles	High	Low	Med	Med	High	Direct input	Survey Questions; Verifier observations
% of Hot Water Washes	Med	Low	Med	Med	High	Will modify savings per cycle	Survey Questions; Verifier observations
Old Consumption	Med	Low	Low	Low	High	Will modify savings per cycle	Literature Review, Verifier observations
New Consumption	Med	Low	Low	Med	High	Will modify savings per cycle	Literature Review, Verifier observations
Efficacy		Low	Med	<u>Med</u>	High		

I.19.8 Results

The engineering realization rate was 133% and was adjusted according to the number of cycles. More research should be conducted to determine representative machine use to verify the savings claim per cycle.

Washing machines were operable; however, as a newer technology, it is unsure if the tenyear estimate of life is representative. The cost for a commercial machine may be somewhat greater than the \$401 incremental cost figure cite in the work papers.

I.20 Insulation (Pipe)

I.20.1 Summary

■ Work Paper Savings Estimates: 3.0 therms/lf/year for hot water pipe, 15.2 therms/lf/year for low pressure steam pipe

New Estimated Savings: 3.0 therms/lf/yr
 Engineering Adjustment Factor: 2.01
 Measure Cost: \$4.39/lf (incremental)

■ Measure Life: 20 years

I.20.2 Prior Savings Estimates

The work paper indicates the savings estimate was based on 2 inches of insulation on a two-inch pipe saving energy for 4200 hours per year and with either 130-degree water or 250-degree steam. The savings appear to be high as they reflect savings on a two-inch pipe, and are particularly high for the hot temperature water application.

I.20.3 New Savings Estimates

Only one site was verified and no meaningful adjustment to the savings estimate was made.

I.20.4 Discussion OF Relevant Variables

Relevant variables are, as stated, temperature and hours of use. However, the size of the line is equally important, and should be segregated.

I.20.5 Work Paper Assumptions

Significant assumptions are related to the size and temperature being constant, or representative of all applications.

- Pipe insulation, hot water application: 130 degree water, two inches of insulation over 2 inch bare pipe; pipe system operated 4,200 hours/year.
- Pipe insulation, low pressure steam application: 250 degree steam, two inches of insulation over two inch bare pipe; pipe system operated 4,200 hours/year.

I.20.6 Work Paper Equation

The work paper equation is not explicitly identified. The source of the point estimates also is not identified. However, according to ASHRAE:

For convection and radiation:

$$\frac{q}{A} \left[\frac{Btu}{h \cdot ft^2} \right] = \left(h_c + h_r \right) \left(T_s - T_{\infty} \right)$$

where

$$h_c = 0.182(T_s - T_\infty)^{1/3}$$
, ASHRAE 2005 Fundamentals, 3.17, T10.15 (turbulent flow)
 $h_r = \varepsilon \sigma (T_s + T_\infty) (T_s^2 + T_\infty^2)$

For the insulated tank, the heat transfer has three components, conduction through the insulation, natural convection off the insulation surface, and radiation off the insulation surface. The heat transfer though the insulation must be equal to the sum of the natural convection and radiation off the insulation surface:

For conduction through insulation:

$$\frac{q}{A} \left[\frac{Btu}{h \cdot ft^2} \right] = \frac{k}{L} (T_a - T_b)$$

In order to find the temperature of the insulation surface, we must iteratively solve the two equations above so that the heat flow through the insulation equals the heat flow from the insulation surface to the room

The difference between the heat flow from the bare tank and the heat flow from the insulated tank is the energy savings resulting from the insulation.

For pipes, we assume the pipes to be a horizontal cylinder.

For the convection and radiation:

$$\frac{q}{L} \left[\frac{Btu}{h \cdot ft} \right] = D\pi \left(h_c + h_r \right) \left(T_s - T_{\infty} \right)$$

where

$$h_c = 0.213 \left(\frac{T_s - T_\infty}{D}\right)^{1/4}$$
, ASHRAE 2005 Fundamentals, 3.17, T10.16 (laminar)
 $h_r = \varepsilon \sigma (T_s + T_\infty) (T_s^2 + T_\infty^2)$

For the conduction through insulation:

$$\frac{q}{L} \left[\frac{Btu}{h \cdot ft} \right] = \frac{2\pi \cdot k (T_a - T_b)}{\ln(D_o / D_i)}$$

Note that to convert the heat loss energy savings to gas savings, we need to include inefficiencies used in heating the working fluid. There is no indication as to whether the work paper savings calculations take this efficiency into consideration. The lower the efficiency of the fluid heater, the greater the gas savings that will result from insulating the system.

I.20.7 Recommendations

Based on the size of this measure relative to other measures, site visits are recommended if a sufficient sample can be recruited.

Table I-44: Collection Methods for Pipe Insulation

		Collection Method				Use in	
Variable	Value	Secondary	Survey	On-Site	M&V	ASHRAE Equation	Source of Data

Engineering Realization Rate	100%

I.21 Insulation (Tank)

I.21.1 Summary

■ Work Paper Savings Estimates: 11.4 therms/sq. ft./year for high temperature solution, 4.1 therms/sq. ft./year for low temperature solution

New Estimated Savings: 22.9 therms/lf/yr
 Engineering Adjustment Factor: 2.01
 Measure Cost: \$4.07/sq. ft. (incremental)

Measure Life: 20 years

I.21.2 Prior Savings Estimates

The work paper indicates the savings estimate was based on 2 inches of insulation over a bare tank for 4,200 hours per year and with either 120 degree solution or 180 degree solution. The savings appear to be high, and are particularly high for the hot temperature water application.

I.21.3 New Savings Estimates

Only one site was verified and the adjustment was made based on annual tank use.

I.21.4 Discussion of Relevant Variables

Relevant variables are, as stated, temperature and hours of use.

I.21.5 Work Paper Assumptions

Significant assumptions are related to the size and temperature being constant, or representative of all applications.

I.21.6 Work Paper Equation

The work paper equation is not explicitly identified. The source of the point estimates also is not identified. However, according to ASHRAE:

For convection and radiation:

$$\frac{q}{A} \left[\frac{Btu}{h \cdot ft^2} \right] = \left(h_c + h_r \right) \left(T_s - T_{\infty} \right)$$

where

$$h_c = 0.182(T_s - T_{\infty})^{1/3}$$
, ASHRAE 2005 Fundamentals, 3.17, T10.15 (turbulent flow)
 $h_r = \varepsilon \sigma (T_s + T_{\infty})(T_s^2 + T_{\infty}^2)$

For the insulated tank, the heat transfer has three components, conduction through the insulation, natural convection off the insulation surface, and radiation off the insulation surface. The heat transfer though the insulation must be equal to the sum of the natural convection and radiation off the insulation surface:

For conduction through insulation:

$$\frac{q}{A} \left[\frac{Btu}{h \cdot ft^2} \right] = \frac{k}{L} (T_a - T_b)$$

I.21.7 Recommendations

Based on the size of this measure relative to other measures, site visits are recommended if a sufficient sample can be recruited.

Table I-46: Collection Methods for Tank Insulation

		C	Collection Met	thod		Use in	
Variable	Value	Secondary	Survey	On- Site	M&V	ASHRAE Equation	Source of Data
Fluid Temperature	High	Low	Med	High	N/A	Direct input (directly affects delta T)	Survey Questions; Verifier observations; measurements
Space Temp	Low	Low	Med	High	High	Direct input (directly affects delta T)	Survey Questions; Verifier observations

Type of Insulation	Med	Med	Med	Med	N/A	Direct input (directly affects k/L)	Survey Questions; Verifier observations; Invoices
Efficacy		Low	Med	<u>High</u>	High		

I.21.8 Results

The engineering realization rate was 201% and was adjusted due to logger hours of use (8,760 verses 4,200 hours per year). It was not adjusted due to higher solution temperature (200 verses 180 degrees).

The 20-year estimate of life may be representative of the true useful life if protective jackets are in place. The cost per square foot estimate appears reasonable but could be significantly higher for specialized industrial insulation.

Table I-47: Summary – Tank Insulation

# of Sites Used in Engineering Analysis	1

Tank Area verified (sq.ft)	34
Savings/sq.ft (therms/yr)	11.4
Savings/sq.ft (therms/yr)	22.9
Engineering Realization Rate	201%

I.22 Process Boilers

I.22.1 Summary

■ Work Paper Savings Estimates: 7,074 therms/yr

New Estimated Savings: 5,375 therms/yr
 Engineering Adjustment Factor: 0.75

Measure Cost: \$6,704/unit (incremental)

■ Measure Life: 20 years

I.22.2 Prior Savings Estimates

The method of calculating the savings estimates are not explicit. However, with an increase of efficiency of 8% and an annual use of 8,760 hours with a loading factor of 30% overall, the savings are realistic for the average size of boiler (3,093MBH).

I.22.3 New Savings Estimates

Additional information collected on the actual sizes of boilers was responsible for the majority of the increase from the work paper estimated savings. As presented in the results section below, the average boiler size was 1,550 MBH, verses 3,093 MBH.

I.22.4 Discussion of Relevant Variables

Besides boiler size, other relevant variables are the increase in efficiency, hours of use and loading factor. These are described in following sections.

I.22.5 Work Paper Assumptions

Below is a summary of significant assumptions affecting the savings estimates contained in the work paper:

 Data based on average equipment characteristics of SoCalGas customer participants for 2001 Express Efficiency Programs (expected to impact average rated input of 976 MBH).

- Average efficiency is greater than 82% (as required by program terms and conditions.
- Applications are primarily industrial.

The work paper savings are consistent with an increase of efficiency of 8% and an annual use of 8,760 hours with a loading factor of 30% overall, but are not explicitly defined.

I.22.6 Work Paper Equation

The equation employed in the work paper was not defined.

However, for the new savings estimates, the following formula was used:

MHB saved = MBH boiler average $\times 10\%$ efficiency increase \times hours / $yr \times loading$ factor

where

```
annual use = actual use from field visits = 2,607 to 8,760 hours loading factor = 65\% to 70\%
```

Alternately, an estimate of MBH savings can be:

$$(MGH / eff_{old} - MBH / eff_{new})$$

Use of this factor yields slightly higher savings.

I.22.7 Recommendations

Itron recommends that the boiler size and underlying use be determined to formulate a valid savings estimate. Variables to be considered are summarized in the following table.

Table I-48: Collection Methods for Process Boilers

			Collection Method				Possible
Variable	Value	Secondary	Phone Survey	Site Visit	M&V	Use	Sources Of Data
Facility Type	Medium	High	High	High	NA	Helps validate LF in equation	Survey Questions; Verifier observations
Load Factor (LF)	High	Low	Low	Medium	High	Directly proportional to savings	Survey Questions; Verifier observations
eff _{old}	Medium	Low	Low	Medium	NA	Determines MBH saved in equation	Survey Questions; Verifier observations
eff _{new}	High	Low	Low	High	High	Determines MBH saved in equation	Survey Questions; Verifier observations
hours/yr	High	Low	High	High	High	Directly proportional to savings	Survey Questions; Verifier observations
Total Accuracy		Low	Medium	<u>High</u>	High		

Based on an evaluation of the variables needed for an accurate estimate of savings and the resources needed to obtain these variables, telephone surveys and on site surveys are the best use of resources to obtain the most relevant data. This would increase the accuracy of savings estimates from a low to a high level.

Specifically, the efficiency of the new boiler, (including the type—condensing verses non-condensing—and the make/model) should be determined. The number of hours per year should also be identified. In the interview, the type of facility and use of hot water can be confirmed.

No direct measurement is recommended due to the overall contribution to the total energy savings (the aggregate portfolio of measures). Direct measurement would yield only an estimate of the load factor or the new equipment efficiency for a few of the participants and this would not be necessarily representative of the entire population.

I.22.8 Results

Savings are lower for process boilers due to the smaller size of installed boilers in the sampled and recruited sites. However, as there were only four sites visited, a larger sample size is needed. Attempts were made to accurately determine the number of hours and the load factor was estimated according to the usage type. Unfortunately, the efficiency of the removed units could not be accurately assessed and an efficiency increase of 10% was assumed for all boilers.

There are significant opportunities to better assess these variables with a larger sample for better energy savings determination.

The listed boiler life appears reasonable; however, the incremental cost may be low for this size of boiler. No details are provided for the cost calculation.

Table I-49: Summary – Process Boilers

J.1 Agriculture (Process Measures)

The following measures are included in the agriculture process work papers:

- Low Pressure Sprinkler Nozzles Utility codes: A40, A41, A42, and A43
- Sprinkler to Micro-Irrigation Conversion Utility codes: A48 through A53
- VFDs for Dairy Pumps Utility code: P11
- VFDs for Injection Molding Machines- Utility code: P1

For all agricultural measures, the coincident diversity factor is:

Ag Coincident Diversity Factor

- = Ag Demand at System Peak Maximum Ag Demand Load
- =0.78

The CDF is an annual average based on PG&E's 1992–95 agricultural rate load research data (Quantum 1996).

J.1.1 Low Pressure Sprinkler Nozzles (Utility Codes: A40-A43; PG&E, SCE, SCG, and SDGE)

This measure shows the savings that can be derived from removing impact driven sprinklers having smooth bore nozzles, which require high water pressures to break up the water stream for area coverage, and replacing the nozzles with low pressure water nozzles, which use various orifice shapes and configurations to obtain the desired water stream break up and area coverage. Pumps operating at the lower pressures provide for energy savings and reduced power demand. The measure can be applied to various irrigation system types in which either manually moved water systems or stationary (solid-set) systems are used for broadcast field irrigation. There are several variables, including pump size, pump flow, pump and motor efficiencies, nozzle shape, required pressure for specific irrigation objectives, and the number of nozzles replaced. The kW demand savings per nozzle-per year is calculated varying on irrigation system type. An overall weighted average was determined for average high and low density portable systems and for solid set systems.

Energy use in kWh/yr was calculated by determining the energy required to pump a unitized amount of water, measured in kWh/acre-feet (kWh/AF), multiplied by the total amount of water in acre-feet pumped per year (AF/yr).

$$kWh/yr = kWh/AF \times AF/yr$$

The energy required per acre-ft. of pumping for irrigation is given by Canessa's equation: a constant, times the total dynamic head (TDH) divided by the overall pump efficiency (OPE).

$$kWh/AF - 1.0241 \times TDH/OPE$$

The 1.0241 constant is the kWh required to lift one acre-ft. of water one foot.

The following assumptions were used for the measure calculation of energy savings per nozzle per year and are based on the average agriculture acre in California:

- Operating pressure decrease is 20 psi or 46.2 feet TDH.
- Overall pumping plant efficiency is 55%.
- Irrigation efficiency is 70%. This is the ratio of beneficially used applied irrigation water to the total amount of applied irrigation water (based on evapotranspiration calculated for typical California agricultural area).
- Pump flow is 7.56 gpm/acre.

- Net water applied varies by region. A matrix is provided based on area and irrigation system type.
- Number of nozzles converted varies with irrigation system type; High (21 nozzle) or low (4 nozzle) density portable system or stationary solid set (35 nozzle) systems.

$$kWh/nozzle yr = (kWh/acre yr)/(nozzles/are)$$

A matrix of average irrigation systems and California regions is provided in the work paper.

Demand savings (kW) are calculated using the following:

HP	= motor horsepower (HP) requirements per acre
TDH	= total dynamic head, pressure drop measured in feet of water,
	assumed 46.2 feet
Q	= pump flow in gpm-acre, assumed average for specific areas and
	specific crops
3960	= 1hp/1 gallon of water mass (33,000 ft-lbs/minute)/ 8.33
	pounds/gallon of water
OPE	= overall pump plant efficiency assumed 55%
HP	= (TDH x Q) /(3960 x OPE)

Kilowatt demand savings per nozzle are calculated as follows:

$$kW/nozzle = (HP/acre \times 0.746 \ kW/HR)/(nozzles/acre)$$

The measure life is eight years (California Measurement Advisory Committee Public Workshops on PY2001 Energy Efficiency Programs). The total incremental cost is \$1.20/nozzle and is based on material (\$0.57/nozzle) and labor to install. Labor costs are based on 2001 agricultural labor costs of \$5/hr + 50% burden = \$7.50/hr labor and 5 minutes to walk from sprinkler to sprinkler in the field and change out the sprinkler head for a labor cost of \$0.63/nozzle.

Energy savings in kWh/nozzle-yr savings for two major climate regions and two system types were given as follows:

Table J-2: Energy Savings from Low Pressure Sprinkler Nozzles

SYSTEM/REGION	Portable	Solid-Set
Central Valley	55 kWh	14 kWh
Coast and Coastal Valleys	12 kWh	10 kWh

The non-coincident demand savings in kW/nozzle-yr savings for two major climate regions and two system types were given as shown in the following table.

Table J-3: Non-Coincident Demand Savings from Low Pressure-Sprinkler Nozzles

SYSTEM/REGION	Portable	Solid-Set
Central Valley	0.0349 kW	0.004 kW
Coast and Coastal Valleys	0.0082 kW	0.0029 kW

The measure life was eight years, material incremental cost was \$0.57/nozzle based on the average of three manufacturer's retail pricing, and a labor cost of \$0.63/nozzle. The total installed cost of a low-pressure nozzle retrofit is \$1.20/nozzle.

Review Results

The assumptions and savings estimates, based on averaged data from other studies, appear to be reasonable. Averages may not, however, adequately represent the installed population, given the limited extent of data from the referenced studies. Average per nozzle kWh and kW savings are based on data from specific regions of California (with varying evapotranspiration rates) and specific crops with varying irrigation water requirements. An in-depth analysis is recommended if the installed population is sufficiently heterogeneous and the impact effects are shown to represent a larger portion of the overall portfolio. Costs in particular may be low, even on an incremental basis.

J.1.2 Sprinkler Irrigation to Micro Irrigation System Conversion (Utility Codes: A48–A53; PG&E, SCE, SCG, and SDGE)

This measure evaluates conversion from conventional sprinkler irrigation to micro-irrigation methods of agriculture irrigation and water delivery. Savings are obtained through reduced pumping pressures and reduced energy consumed resulting from overall reduced quantity of water pumped.

The benefits of micro-irrigation include higher irrigation delivery efficiency to crops with direct delivery to plants, minimizing the adverse effects of wind and reducing evapotranspiration (water loss), as well as improved control of irrigation, better delivery of fertilizers, reduced water use, reduced aquifer pumping costs, uniformity of harvest, and better yields.

The calculations for savings include the energy reduction and costs for both the pumping of water from the source aquifer to deliver water to the irrigation system (kWh_{delivery}/AF) and the "boost" irrigation pumping energy and costs to deliver water to the crop (kWh_{boost}/AF).

$$kWh/AF = kWh/AF_{delivery} + kWh/AF_{boost}$$

The primary water source and the delivery method to the irrigation distribution system do not change, but the quantity of water pumped from the aquifer or other source will be reduced.

The following terms are used to calculate energy savings:

kWh/yr = Total annual energy use

kWh/AF = Average amount of energy required to pump an acre-ft. of water

AF/yr = Total acre-feet pumped annually

TDH = Total dynamic head pressure required to pump water through the

irrigation (ft.)

OPE = Overall pumping plant efficiency expressed as a decimal (0.0 - 1.0)

1.0241 = The kWh required to lift one acre-ft. of water one foot.

 $kWh/AF = 1.0241 \times TDH/OPE$

kWh/AF = 1.0241 x TDH/OPE

AF/yr = Annual acre-feet per year of pumped water required to irrigate a cropped

field

Acres = Net cropped acres in the field requiring irrigation

ETc = Net annual water use in acre-feet/acre-year (irrigated or from rainfall)

Rain = Annual rainfall effective in satisfying ETc or required leaching in acre-

feet/acre-year

LR = Leaching requirement for maintaining a salt balance in the root zone

expressed as a decimal (0.0 - 1.0)

IE = Irrigation efficiency as a decimal (0.0 - 1.0)

CL = Conveyance losses in acre-feet/yr, losses delivering water from the

aquifer to the irrigation delivery system.

AF/yr = CL + (acres x [(ETc-Rain)/((1-LR) x IE)]

Calculated savings are annual energy savings equal current energy use minus predicted energy use after installation of the micro-irrigation system.

 $kWh \ saved/year = kWh \ baseline/year - kWh \ projected/year$

Sprinkler irrigation systems are estimated to be 70% efficient and micro-irrigation systems are estimated to be 80% efficient.

Table J-4: Annual kWh/Acre-Year Savings: Water Supply Other Than a Well

Region	Field/Vegetables	Trees	Grape
Central Valleys	579	819	663
Coastal	368	546	381
Central Valleys	615	868	703
Coastal	400	593	415

Table J-5: Annual kWh/Acre-Year Savings: Well as Water Supply

Region	Field/Vegetables	Trees	Grape	
Central Valleys	579	819	663	
Coastal	368	546	381	
Central Valleys	615	868	703	
Coastal	400	593	415	

Changes in Peak kW

The following equation is used to identify the required system flow on a per acre basis:

$$FLOW = 452.5 \times ET_{\text{max}} / (IE \times HOURS)$$

where:

FLOW = Gallons/minute per acre to replace maximum daily crop water use.

 ET_{max} = Maximum daily crop water use in inches/day. IE = Irrigation efficiency as a decimal (0.00 - 1.00).

HOURS = Daily hours of operation.

The required connected load on a per acre basis can be calculated the equation:

$$kW/AC = .746 \times FLOW \times TDH/(3960 \times OPE)$$

where:

kW/Ac = Kilowatt-hours required per acre.

FLOW = Gallons per minute per acre in pumping plant.
 TDH = Total dynamic head of pumping plant in feet.

OPE = Overall pumping plant efficiency as a decimal (0.0 - 1.0).

The connected load reduction is calculated as follows:

$$kWh_{reduced} = kWh_{base} - kWh_{project}$$

Table J-6: Coincident/Non-Coincident kW/Acre Reduction for Converting from Sprinkler Systems to Micro-Irrigation

Region	Field/Vegetables	Trees	Grape		
Central Valleys	0.429	0.380	0.262		
Coastal	0.325	0.288	0.198		

The average measure life is given as 20 years and the installed cost per acre as \$300 per acre.

Review Results

The assumptions and savings estimates, based on data from other studies, appear to be reasonable. Averages may not, however, adequately represent the installed population, given the limited extent of data from the referenced studies. Average per acre kWh and kW savings are based on data from specific regions of California (with varying evapotranspiration rates) and specific crops with varying irrigation water requirements. An in-depth analysis is recommended if the installed population is sufficiently heterogeneous and the impact effects are shown to represent a larger portion of the overall portfolio. The efficiencies of the two types of systems should be thoroughly examined.

J.1.3 VFDs for Dairy Pumps (Utility Code: P11; SCG and SDGE)

The measure describes savings that may be obtained at dairy operations from retrofit of constant speed commercial pump motors with variable frequency drive (VFD) or variable speed drive (VSD) controllers. The VFDs provide milk pumping speeds that match the required pumping to the available milk supply or load. Milk pumps with VFDs that speed up or slow down the pump motor, depending on the amount of milk in the receiver, are more efficient. A more uniform flow through the plate cooler also increases its effectiveness. An average energy savings value of 3730 kWh/hp was given with an average pump size of 12 hp (ranging from 5 to 20 hp).

References provided include the Centre for the Analysis and Dissemination of Demonstrated Energy Technologies (CADDET), the PG&E Standard Performance Contract (SPC) program, and the Southern California Edison (SCE) Savings by Design (SBD) program and associated software.

The VFDs for Dairy Pumps measure found in the Express Efficiency work papers for SCG and SDGE is not included in the work papers for PG&E or SCE. The SCE Savings By Design (SBD) program is a reference for this work paper. The work paper also presents savings data that were used in the PG&E SPC Program.

Review Results

The assumptions for the savings calculation appear reasonable and are based on the referenced sources and dairy equipment retail vendors. Explicit calculations are not provided except for the estimated payback period based on normalized or average numbers. The work paper should be modified to include explicit calculations showing how savings are obtained. An in depth analysis is required for verification and baseline data would be particularly helpful. There may be a wide range of savings estimates based on loading profiles and hours of usage.

J.1.4 VFDs for Injection Molding Machines (Utility Code: P1; SCG and SDGE - Struck out in PGE Work papers)

Plastic IMMs are used to fabricate plastic milk containers and it is presumed IMMs are grouped with the Agriculture Process measures for that reason.

The use of VFDs on Injection Molding Machines (IMMs) can significantly improve pump motor efficiency within the injection mold cycle and can reduce their energy consumption by 20-60%. Many IMMs operate at relatively low efficiencies. The VFDs provide pumping speeds that match the pumping required to the varying load, including idle time where no pumping power is required.

References include San Francisco State University Industrial Assessment Center (SFSU IAC), the San Diego State University Industrial Assessment Center (SDSU IAC), Pacific Gas & Electric Standard Performance Contract (SPC) program, and Magnum LLC (a VFD manufacturer). It is estimated that the IMM operates with an idle time of 20% of the total cycle time. Cost estimates for VFDs were calculated based on information provided by the previously listed sources. The measure includes a table showing the average cost per horsepower for a VFD system installation (listed at \$216/hp). The estimated average demand savings is 0.22 kW/hp.

An economic analysis provides a summary of simple payback based on various demand saving studies, installation costs, and rebate levels. Regardless of the rebate level for the measure, in general, if annual operation is greater than 6000 hours, the simple payback will be one year or less. The actual payback also will vary depending on the application and the specific part being molded. The following equation shows how the payback period is calculated:

$$Payback\ Period = \frac{(VFD\ Cost\ -\ Rebate)}{\left(Average\ Demand\ Savings \times Annual\ Operation\ \right) \times Energy\ Rate}$$

$$Payback\ Period = (\$216/hp\ -\$65/hp) \div (0.22\ kW/hp\ \cdot 7000\ hr/yr) \div \$0.128/kWh$$

 $Payback\ Period = 0.77\ years$

The measure does not explicitly state what incentive will be applied, but references the SCE incentive rate (\$/hp) of 30% of the total VFD cost and references the 2001 PG&E SPC program, which offered an incentive of \$150 per kW saved.

Review Results

The savings calculation methodology appears appropriate. The assumptions are based on industry averages and averages of data from injection molder studies. These assumptions should be verified periodically in order to assess the accuracy of the savings estimates. An in depth analysis is required for verification. Using an average 20% idle time, representative hours and representative parts molded allows the savings calculations and incentive levels to be applied under the Express Efficiency Program.

J.2 Building Shell

J.2.1 Cool Roofing

The savings estimated for this measure is 0.5 kWh per sq. ft. per year based on the average savings value of 0.31 kWh per year for climate zones 2-15 (according to a LBNL new construction study conducted as part of the Title 24 update process – see *PG&E 2005 Title 24 Building Energy Efficiency Standards Update; Code Change Proposal: Inclusion of Cool Roofs in Nonresidential Title 24 Prescriptive Requirements; Revised August 2002*). multiplied by a factor of 1.6 to account for the additional savings expected in retrofit situations. The multiplier is based on actual measurements of air conditioning savings in existing buildings retrofit with a cool roof; these measurements show a wide range of savings (2% to 60%), depending on climate zone, existing roof construction, and building utilization. Program rules exclude roofs with an existing radiant barrier and buildings in climate zones 1 and 16 (due to low savings potential in these climate zones). It is noted in the work papers that buildings with large amounts of existing insulation have a lower cool roof savings potential, but no adjustment or exclusion is made for buildings with high levels of pre-existing insulation. The kW savings figure of 0.0003 per sq. ft. has been taken from the LBNL study; this figure was also multiplied by 1.6 to account for retrofit construction.

An addendum to the work paper uses the DOE Cool Roof Calculator (developed by Oak Ridge National Laboratory) to specify savings for each climate zone individually. The baseline for this calculation is an uncoated asphalt surface with a solar reflectance of 0.05 and an infrared emittance of 0.90. The building is air conditioned with equipment that has a coefficient of performance (COP) equal to 2 and a roof R-value of 10. The simulation involves changing the solar reflectance to 0.50 and infrared emittance to 0.60. Savings for

climate zones 2-15 range from 0.03 kWh/ft^2 (climate zone 5) to 0.88 kWh/ft^2 (climate zone 15).

Incremental costs of \$0.32/sf and a life of 15 years is given.

Review Results

Savings estimates appear to be reasonable. The insulation level set in the addendum calculations (R-10) is reasonable for a flat roof on an existing building in California. The cool roof solar reflectance (0.50) and infrared emittance (0.60) values used in the addendum simulation are given in the calculator as average values, and are appropriate for an aluminum roof coating; however, newer white cool roof materials have higher initial non-weathered solar reflectance (0.80) and infrared emittance (0.90) values, as compared to the values used in the calculator. The average solar reflectance (0.50) and infrared emittance (0.79) for all Energy Star cool roofing products yield savings different than those listed in the addendum. In addition, accurate assessment of baseline roofing materials and insulation R values are very important to determine accurate savings. An in-depth evaluation is required to determine the magnitude of the change from these modifications. There may be wide variability in energy savings at the site level and from predicted program averages /population impacts. Incremental costs may be reasonable: however, a life of 15 years may be high, as it may not account for weathering effects for a majority of the cool roofing products and for low slope roofs.

J.2.2 Infrared Film for Greenhouse Walls and Roof

The baseline for this measure incorporates a pre retrofit baseline of a greenhouse with non-IR film characteristics (U value \geq 40) for prototypical greenhouses in San Diego and Oxnard (100 ft. by 30 ft., plastic sheeting for walls/roofs, and 7 ft. walls). The post installation condition assumes a greenhouse with the same dimensions and envelope fitted with plastic film with IR film characteristics (U value \leq 20). The thermal performance of each is evaluated and compared to derive energy savings.

The work paper energy savings for these measures were estimated using the Energy Pro model for the pre and post measure installation. Reported gas heating savings were 50% for the San Diego climate and 56% for the Oxnard, California climate. Actual empirical testing performed and documented in the American Society of Agricultural Engineers (ASAE) Paper No. 84-4033 "Evaluation of and Experimental Greenhouse Film with Improved Energy Performance" (dated June 24-27, 1984) indicated 35% less energy consumption for greenhouses equipped with IR film. Differences between model and empirical test results are attributed to probable infiltration rates and leakage from greenhouses. The conservative 35% of baseline model energy consumption for the two weather regions selected was used for energy savings. Savings in therms per sq. ft. of installed film was calculated for the building

total surface area. Effective useful life of IR film is 4 years and the incremental cost is \$0.03 per sq. ft. Savings (in therms per sq. ft.) were 0.049 therms per sq. ft. for San Diego and 0.057 therms per sq. ft. for Oxnard.

Review Results

Savings estimates and assumptions appear to be reasonable. Additional accuracy in the savings calculations by could be obtained by comparing, and revising if necessary, the prototypical greenhouse used in the simulation with actual program participants' facilities. An in-depth analysis is required for verification. There may be wide variability in energy savings at the site level and from predicted program averages. Details of the empirical testing by the ASAE are not provided in the work paper. The energy savings are based on therms per sq. ft. and the total sq. ft. film surface area for two climate zones. Verification of this measure would likely require an in-depth review of the simulation models.

J.3 Food Service

J.3.1 Ice Machine -Commercial (SCE)

The measure is covered by SCE work papers only; the SCE work papers reference the PG&E Food Service Technology Center (FSTC) estimates for ice machines in California. The work paper evaluates replacement of older air-cooled ice machines with new, more efficient, air-cooled units. Commercial icemakers represent approximately 11 % of all commercial refrigeration energy use with average annual energy consumption of 5,000 kWh for a 500lb/day machine. The ice machines presented range from 101 to greater than 1,500 lbs per day (24 hour) production or harvest rate.

Ice makers use a substantial amount of energy in order to freeze water and maintain the ice as separate cubes. Replacement of older units provides a potential for 15% energy savings. Reductions are possible with the use of high efficiency motors in condenser fans and compressors, thicker insulation and reduced evaporator thermal cycling. The energy use in a commercial icemaker varies from product to product, depending on the condenser and the type of ice produced. For eligibility, customers must provide proof of compliance with the program's energy efficiency specifications for various specific sizes of ice machines based on lbs/day ice harvest rate. The efficiency specification is an adapted version of the Federal Energy Management Program (FEMP) specification. The measure references American Refrigeration Institute (ARI) Standard 810 for performance.

The SCE work paper provides a table or matrix of cost effectiveness and compares baseline energy and energy efficient appliance use, energy savings, demand savings, and estimated cost savings based on the sizes (in ice harvest rate, or IHR) of the ice machines. The highest performing models on the market are greater than 18 % more efficient than the worst

performing models. Ice machine operating hours are assumed to be 3,000 hours per year. The estimated useful life is 12 years for new air-cooled ice machines of all size classifications.

The work paper includes a table with various manufacturers and models of energy efficient units, their harvest rate (size), and their relative cost. These are compared with manufacturers' costs of baseline units. Savings are based on simple energy efficiency savings of new energy efficient air-cooled units over older, less efficient units. Specific energy savings calculations are not provided and may be calculated or empirical.

Review Results

The measure provides the basis for savings with straightforward comparative examples of old and new ice machines. An efficiency incentive threshold (in kWh/100lbs of ice) for the various size units is provided in a cost effectiveness matrix. The basis of savings appears to be from FEMP, and the maximum savings level of 18.46% cited appears reasonable for peak demand. However, this appears to be applied to kWh savings and this should be examined more closely. Additionally, there appears to be incorrectly high levels of savings for machine less than 300 pounds per day. A more detailed review of the FEMP documentation and calculation methodologies would need to be performed to determine actual savings. A lifetime of 12 years and costs given appear reasonable.

J.3.2 Insulated Holding Cabinet

Commercial insulated hot food holding cabinet models that meet program requirements incorporate better insulation, reducing heat loss, and may offer additional energy saving devices such as magnetic door electric gaskets, auto-door closures, or Dutch doors.

Savings for the insulated hot food holding cabinets are derived from the comparison of baseline cabinet energy use to comparable size and energy use of energy efficient full size, three-quarter size and half-size holding cabinets. The SCE work paper also provides measure description, market applicability, terms and conditions, and cost effectiveness modeling measure data with tabulated examples comparing baseline units to new, more efficient units in the full, three-quarter, and half cabinet sizes. The maximum idle energy use rate is required to be a maximum of 20 watts/cubic ft. of cabinet space for all size classes. The ENERGY STAR® specification for hot food handling cabinets, accepted by the California Energy Commission, has a maximum idle energy rate (MIER) of 40 watts. All IOU work papers reference the ASTM Standard F2140 for operating energy performance of full size holding cabinets.

Review Results

The measure provides the basis for savings with a straightforward reduction of 50% from 0.8 kW, 0.6 kW and 0.4 kW for different size cabinets, along with 15 hours per day for 365 days per year for energy calculations. Both the efficiency increases and hours of use appear high. A lifetime of 12 years and costs given appear reasonable.

J.3.3 Pressureless Steamers

Pressureless steamers are described and an example of a baseline unit and an energy efficient model are given in the PGE work papers. A summary table lists estimated energy and power savings (12.5 kW; 11,166 kWh/yr), equivalent full load operating hours (12 hours per day, 365 days per year), and effective useful life (12 years EUL). Incremental costs are listed as \$4,150 / unit.

Savings for pressureless steamers are based on higher efficiency (50% and 70%) of new units compared with the efficiency (26% to 30%) of the existing or baseline units and are also based on a lower idling rate of 0.4 kW (verses a baseline of 1.0 kW).

The PGE work paper for the pressureless steamers provides discussion about the variability of steam systems for cooking large quantities of food. This discussion is not included in the work papers of all the utilities. Information about the ASTM Standard Test Method for the Performance of Steam Cookers (F1484) dated 2005 is referenced in the work papers. These standards quantify the efficiency and performance of steamers. The PGE work paper covers the effect of the increased efficiency of the newer units on water and sewer costs.

Review Results

The energy consumption calculation for pressureless steamers in the SCE work paper is unclear. Equipment ratings are based on food service equipment industry representative example units. The assumptions should be verified in order to assess the accuracy of the savings estimates. An in depth analysis is required for verification. There may be wide variability in energy savings at the site level and from predicted program averages due to varying baselines for actual installed equipment. Annual use at 12 hours per day for 365 days per year may be high and should be examined. Costs and measure life appears reasonable.

J.4 Air Conditioning Measures

J.4.1 Package Terminal A/C Unit (PTAC) [PG&E and SCG]

Package terminal air conditioners (PTACs) and package terminal heat pumps (PTHPs) are through-the-wall units usually in the 0.5 to 1.5 ton cooling capacity range. These units cool

small areas and are commonly used for individual rooms. PTACs and PTHPs are usually associated with motels and hotels where the individual control permits efficient operation in structures that have wide swings in occupancy levels. They are also widely used in apartments and small office buildings.

Package terminal, air-cooled, air conditioners in this size range are rated according to California state standards (in EER). The kW calculation shown below is an accepted equation for kW, tons, and EER.

$$EER_{base} = 10.0 - (0.16 \times Capacity / 1000)$$

Capacity is in Btu/hr (for capacities less than 7,000 Btu/hr, EER is calculated using 7,000 Btu/hr.

$$kW = 12 \times Tons / EER$$

The measure demand reduction estimate is based on averaging several examples of sizes and efficiencies above the baseline unit. The baseline formula is consistent with the California minimum efficiency standard currently in effect for this size and type of equipment.

$$Measure\ Demand\ Reduction = kW_{title20}\ - kW_{premium-efficiency\ unit}$$

Energy savings are calculated by multiplying the measure demand reduction with the equivalent full load cooling hours (EFLCH):

- Annual Energy Savings = Measure Demand Reduction x EFLCH.
- Coincident demand reduction is calculated by multiplying the measure demand reduction with the coincident diversity factor (CDF) for each market segment.
- Coincident Demand Reduction = Measure Demand Reduction x CDF.

Review Results

Savings estimates of 0.156 kW/ton appear to be reasonable. An in depth analysis is required for verification. However, given the range in hours of operation (EFLCH) by building type, as well as the high level of understanding of these systems, there is not expected to be wide variability in these systems.

J.4.2 Direct Evaporative Cooler [PG&E and SCE]

This measure is for the replacement of an existing vapor-compression piece of air cooling equipment (typically package units) with direct evaporative cooling units. The peak demand reduction (kW) and annual energy savings (kWh) are the difference in consumption between

operating an air conditioning unit and a direct evaporative cooler. Generally, the customers who apply for this measure are small commercial and industrial customers with non-constraining humidity requirements.

Direct evaporative coolers contain evaporative pads. A water-circulating pump lifts the sump water to distributing system, and it flows down through the pads back to the sump. A fan within the cooler pulls the air through the evaporative pads and delivers it to the space to be cooled. Direct evaporative cooling efficiency depends upon the outdoor wet bulb temperature and humidity level. If an evaporative cooler is used in an inappropriate climate, it may not have the ability to cool but instead raise the humidity level in the room. Therefore, the analysis is based on selected applications (low comfort occupancies).

Low comfort occupancies would be considered to occur at internal design conditions of 84°F, 60% RH, when conditioned (high comfort occupancies would be considered to have an internal requirements of 76°F, 60% RH when conditioned). Energy savings and demand savings were based on design conditions in the California Energy Commission climate zones corresponding to PG&E's service territory.

Demand reduction by climate zones for a 10-ton capacity unit are shown in the table below and normalized per ton based upon these temperature differentials and an assumed conventional HVAC system efficiency of 1.3 kW/ton. The energy savings are based on cooling degree days (CDD, base 65°F) in each of the CEC climate zones.

Table J-7: Demand Reduction and Energy Savings Per Ton

CEC Climate Zones	2	4	5	11	12	13	16
Demand Reduction (kW)	1.04	.93	1.11	0.97	0.95	0.65	1.01
Cooling Degree Hours (65°F)	1,003	861	493	1,729	1,331	2,252	720
Energy Savings (kWh/yr.)	1,043	801	547	1,677	1,265	1,464	727

Data from prior rebate programs were used to determine average sq. ft. feet and location of applications. The main market sectors applying for evaporative coolers are the industrial warehouse, hotel/motel, retail, and restaurant sectors. The average square footage was 5,000 sq. ft. This corresponds to an air-conditioning load of 10 tons. It is not recommended to use evaporative cooling in CEC Climate Zones 1 and 3 due to outdoor temperatures and humidity conditions that are not suitable for effective evaporative cooling.

Equipment cost is \$1,269 for a 10-ton unit based on 1991 Means Mechanical Estimating Manuals. Costs are for equipment and labor including installation and auxiliaries. This corresponds to \$127 per ton.

Review Results

Savings estimates appear to be reasonable, but may not be representative for all climate zones. The equipment cost value of \$1,269 for a 10-ton unit is based on a 1991 value which may be different than the current cost. Savings values should be verified, especially for climate zone 13, for which the kW savings are lower than for other climate zones while the annual kWh savings are higher than for those climate zones.

J.5 Lighting

J.5.1 Ceramic Metal Halide Fixtures

The ceramic metal halide (CMH) fixtures and lamps are expected to be utilized primarily in retail settings to replace inefficient halogen lamps (and to a lesser extent, incandescent). The 39-watt PAR CMH fixture consumes a total of 44 watts, while the 90-watt PAR halogen fixture consumes 90 watts. The difference is 46 watts. A 70-watt CMH would replace two 90-watt halogen lamps. There are assumed to be a tiny fraction of incandescent lights still in use (4%) which were represented as 150 watt fixtures replace by 39 watt CMH fixtures. The savings are 46 watts, 98 watts, and 106 watts for each of these cases. Based on the percentages of installed cases, the average reduction is 73.3 watts; the retail hours of operation of 4,717 hours per year, and the coincident diversity factor of 1.00 yields 346 kWh/yr of savings. A wide range of costs from \$242 to \$410 per fixture is given.

Review Results

Savings and cost estimates appear reasonable. However, the baseline fixtures should be better quantified and correlated to relevant lighting codes as applicable.

J.5.2 Induction Fixture

The work paper assumes baseline calculations are for replacement of 75 watts of incandescent lighting with 23 watts of induction lighting. In this instance, the typical replacement will be of a medium-socket R-type reflector lamp in a recessed down light or track light. The induction lamp with integral generator consumes 23 watts. Total installed wattage drops from 0.075 kW to 0.023 kW. The measure assumes that the predominant market sectors are office, school, college, and retail. The product life is 15,000 hours (lamp and generator unit) with an incremental cost of \$14. The non-coincident demand savings are 0.052 kW and the coincident demand savings vary by specific market sector hours of operations. Savings are achieved by reduced wattage from incandescent to induction lamp/ballast screw in unit.

More prevalent incandescent retrofits may involve higher wattages. This baseline assumes a 50 - 50 split between 200 watt and 300 watt incandescent lamps replaced with 55 watt and

85 watt induction lamp fixtures. The average total installed wattage drops from 0.250 kW to 0.070 kW. The work paper energy savings are achieved by use of lower wattage fixtures and lamps in specific applications. The measure assumes that the predominant market sectors are school, college, warehouse, assembly and process industries, and retail. Fixture life is listed as 16 years with an incremental cost of \$295. Non-coincident demand savings are 0.180 kW and coincident energy savings are modeled on the various market sector based operating hours.

For the retrofit of existing mercury vapor lighting, the baseline assumes the replacement of 250 watts of mercury vapor lighting with 150 watts of induction lighting. The mercury vapor wattage with ballast is 290 watts. The induction lamp system wattage is 157 watts. Total installed wattage drops from 0.290 kW to 0.157 kW. Non-coincident demand savings are 0.133 kW and coincident energy savings are modeled on the various market sector based operating hours

Review Results

Savings estimates appear to be reasonable. More accurate demand savings may be derived from actual field data for wattages replaced, installed wattages, and hours used. An in depth survey is required for verification.

J.5.3 Channel Sign Light Emitting Diode (LED)

This measure is for a retrofit of existing neon sign lighting. The baseline assumes the replacement of neon lamps (depending on height of the sign) consuming 11.4 watts per linear ft. of sign with letters under 2 feet high and 22.8 watts per linear ft. for signs with letters greater than 2 feet high. These are replaced with red LEDs installed to provide equivalent luminance with power demand in the range of 0.9 to 1.2 watts per ft., offering a demand reduction of 10 watts per linear ft. of sign for signs under 2 feet high and 20 watts per linear ft. for signs greater than 2 feet high. Other LED colors demand slightly less or more power, ranging from 0.5 watts per ft. to 2 watts per ft. for equivalent luminance. LEDs demand significantly less power than neon lamps. The measure assumes that the predominant market sector is commercial (retail, grocery, restaurant, and hotel/motel). Fixture life is listed as 16 years for consistency with other lighting measures in the work papers; actual fixture life is anticipated to be approximately 50% longer. The retrofit incremental costs are listed at \$18 per linear ft. for signs less than or equal to 2 feet in height and \$33 per linear ft. for signs greater than 2 feet in height. For sign replacement applications, the incremental cost is the \$12/ft. and \$24/ft. LED cost for the ≤ 2 feet and ≥ 2 feet high sign respectively.

Coincident energy savings are modeled on the retail/commercial market sectors for indoor and outdoor signs with 12 hours of operation (between 10 a.m. and 10 p.m.); for indoor

signs with a coincidence of 1.0 and 8 hours of operation (between 4 p.m. and 12 a.m.). For outdoor signs, there is zero coincidence with afternoon peak demand periods (as expected).

Annual energy savings for indoor signs ≤ 2 feet high are 43.8 kWh/ft. (10 watts x 12 hours x 365 days/1000) and for signs ≥ 2 feet high are 87.6 kWh/ft. For outdoor signs, the savings are 21.9 kWh/ft. (10 watts x 6 hours x 365 days/1000) and 43.8 kWh/ft. for the smaller and larger signs, respectively.

Review Results

Savings estimates appear to be reasonable based on linear feet of sign lighting, although alternate projections may exist for hours of lighting use. Costs appear reasonable but should be updated.

J.5.4 Metal Halide (MH) Fixtures

Metal halide fixtures demand less power than incandescent or mercury vapor lamps for comparable or better efficacy. It is assumed that the predominant market sectors are school, college, warehouse, assembly/process industries, and retail. Demand reductions vary according to market sector usage differences. Separate savings are projected for all market sectors based on varying operation hours.

- L185 or L186: Interior HID Fixtures (Compact): 0–35 Lamp Watts.
- Conversion from a 100 watt Incandescent Fixture or Conversion from a 50 watt Mercury Vapor Fixture to a 35 watt MH fixture.
- L187 or L188: Interior HID Fixtures (Compact): 36-70 Lamp Watts.
- Conversion from a 200 watt Incandescent Fixture or Conversion from a 100 watt Mercury Vapor Fixture to a 70 watt MH fixture.
- L189 or L190: Interior HID Fixtures (Compact): 71-100 Lamp Watts.
- Conversion from a 300 watt Incandescent Fixture or Conversion from a 175 watt Mercury Vapor Fixture to a 100 watt MH fixture.

Total installed wattage drops as follows for the following cases:

- L185: from 0.100 kW to 0.045 kW
- L186: from 0.074 kW to 0.045 kW
- L187: from 0.200 kW to 0.090 kW
- L188: from 0.125 kW to 0.090 kW
- L189: from 0.300 kW to 0.129 kW
- L190: from 0.200 kW to 0.129 kW

For non-coincident demand reductions and with incremental costs of:

- L185: 0.055 kW Incandescent base case incremental cost \$133
- L186: 0.029 kW Mercury vapor base case incremental cost \$60
- L187: 0.110 kW Incandescent base case incremental cost \$287
- L188: 0.035 kW Mercury vapor base case incremental cost \$287
- L189: 0.171 kW Incandescent base case incremental cost \$287
- L190: 0.071 kW Mercury vapor base case incremental cost \$287

Demand reductions vary according to market sector usage differences. Separate savings are projected for all market sectors based on varying operation hours.

Review Results

Savings estimates appear to be reasonable. The incandescent wattages in particular should be examined to determine the applicable baseline, and lighting codes should also be factored into the baseline calculations. Costs are reasonable in most instances cited; however, an incremental cost of \$60 for the mercury vapor conversion may be high. The range of fixture wattages for the metal halide fixtures may also be better defined by identified specific wattages available.

J.5.5 Pulse Start Metal Halide Fixtures

Metal halide fixtures demand less power than incandescent or mercury vapor lamps for comparable or better efficacy. Savings are achieved by use of lower wattage fixtures and lamps. The measure assumes that the predominant market sectors are school, college, warehouse, assembly and process industries, and retail. Demand reductions vary according to market sector usage differences. Savings are projected for all market sectors based on varying operation hours of savings.

Interior Pulse Start Metal Halide Fixtures

- L191 or L192: Interior HID Fixtures (Pulse Start): 101–175 Lamp Watts.
- Conversion from a 500 watt Incandescent Fixture or Conversion from a 250 watt Mercury Vapor Fixture to a 175 watt MH fixture.
- L193 or L194: Interior HID Fixtures (Pulse Start): 176-250 Lamp Watts.
- Conversion from a 750 watt Incandescent Fixture or Conversion from a 400 watt Mercury Vapor Fixture to a 250 watt MH fixture.
- L195 or L196: Interior HID Fixtures (Pulse Start): 251-400 Lamp Watts.

■ Conversion from a 1000 watt Incandescent Fixture or Conversion from two 400 watt Mercury Vapor Fixtures to one 400 watt MH fixture.

Total installed wattage decreases for the following measures as follows:

- L191: from 0.500 kW to 0.208 kW
- L192: from 0.285 kW to 0.208 kW
- L193: from 0.750 kW to 0.288 kW
- L194: from 0.454 kW to 0.272 kW
- L195: from 1.00 kW to 0.366 kW
- L196: from 0.908 kW to 0.460 kW

For non-coincident demand reductions and costs are as follows:

- L191: 0.292 kW Incandescent base case incremental cost \$287
- L192: 0.077 kW Mercury vapor base case incremental cost \$287
- L193: 0.462 kW Incandescent base case incremental cost \$287
- L194: 0.182 kW Mercury vapor base case incremental cost \$287
- L195: 0.634 kW Incandescent base case incremental cost \$287
- L196: 0.483 kW Mercury vapor base case incremental cost \$287

Review Results

Savings estimates appear to be reasonable. Baseline equipment could be better defined. The flat incremental cost of \$287 seems high (for true incremental costs) and may vary across size of fixtures. The titles give a range of lamps but savings are presented for only one lamp size, corresponding to the largest size in the range. The titles may be modified to better reflect the actual calculations.

Exterior HID Fixtures 0-100 Watts

- L197 or L198 Conversion from a 300 watt Incandescent Fixture or Conversion from a 175 watt Mercury Vapor Fixture to a 50-50 split of 129 watts of metal halide (MH) and 95 watts of high pressure sodium (HPS) fixtures and lamps.
- Exterior HID Fixtures: 101–175 Lamp Watts.
- L199 or L200 Conversion from a 500 watt Incandescent Fixture or Conversion from a 250 watt Mercury Vapor Fixture to a 50-50 split of 210 watts MH and 130 watts of HPS fixtures and lamps.
- Exterior HID Fixtures: ≥176 Lamp Watts.

- L201 or L202 Conversion from a 750 watt Incandescent Fixture or Conversion from a 400 watt Mercury Vapor Fixture to a 50-50 split of 295 watts MH and 240 watts of HPS fixtures and lamps.
- Exterior lights are assumed to be controlled by time clocks and photocells. Hours of operations for all market sectors are 4,100 hrs/yr.

Total installed wattage drops:

- L197: from 0.300 kW to 0.112 kW
- L198: from 0.200 kW to 0.112 kW
- L199: from 0.500 kW to 0.170 kW
- L200: from 0.285 kW to 0.170 kW
- L201: from 0.750 kW to 0.268 kW
- L202: from 0.454 kW to 0.268 kW

For non-coincident demand reductions of:

- L197: 0.188 kW Incandescent base case incremental cost \$144
- L198: 0.088 kW Mercury vapor base case incremental cost \$144
- L199: 0.330 kW Incandescent base case incremental cost \$144
- L200: 0.115 kW Mercury vapor base case incremental cost \$144
- L201: 0.482 kW Incandescent base case incremental cost \$144
- L202: 0.186 kW Mercury vapor base case incremental cost \$144

Exterior metal halide and high pressure sodium fixtures demand less power than incandescent or mercury vapor lamps for comparable or better efficacy. Work paper savings are calculated by use of lower wattage fixtures and lamps on the 50-50 split between MH and HPS fixtures. The source of the calculations for the work papers is not noted. The measure assumes that all market sectors have the same hours of use for exterior lighting and thus the energy savings are projected for all market sector as follows:

- L197: 771 kWh/yr
- L198: 361 kWh/yr
- L199: 1,353 kWh/yr
- L200: 472 kWh/yr
- L201: 1,976 kWh/yr
- L202: 763 kWh/yr

Review Results

Savings estimates appear to be reasonable. More accurate savings would be determined using specific hours of operation for each sector. Costs can be refined from flat incremental costs of \$144 for all types and sizes of fixtures.

J.5.6 Occupancy Sensors: Plug Load Sensor [PG&E, SCE, SCG, and SDGE]

This work paper entails occupancy sensor control of one 50-watt task light and one 100 watt computer monitor in a private office or cubicle through an infrared or ultrasonic plug sensor associated with a power strip for desk top/workspace/task loads. For this measure, it is assumed the occupancy sensor turns off equipment for 2,450 hours/year (66% reduction over manual switching). The source of the calculations for the work papers is not noted. The measure assumes that all market sectors have the same hours of use for this measure and thus the same savings are projected for all market sectors with the predominant application in office buildings. The sensor life is listed as eight and the incremental cost is \$20.

The non-coincident demand savings are 0.099 kW when shutting off equipment (0.150 kW x 66% reduction in hours). The coincident demand savings are 0.124 kW (0.099 kW x 1.25 average office sector demand interactive effects factor) and energy savings are 290 kWh per year for all market sectors which includes 17% average office sector energy interactive effects.

Review Results

Savings estimates appear to be reasonable, however assumptions about periods when equipment is turned off may be overstated and savings may be greater or less than projected by the work papers depending on the specific application. An in depth analysis is required for verification. Baseline energy use given the status of computer monitor sleep modes and energy consumption must be examined.

J.5.7 Photocell

This work paper describes an exterior lighting control application for photocells used in conjunction with time clocks to limit automatically energized exterior lighting when illumination levels are adequate. The interior application is not described in detail, but mentions lighting savings related to photocell control of fixtures near skylights and windows, de-energizing lighting when interior illumination levels reach a set limit. The work paper example calculation describes outside lights controlled by a photocell in conjunction with a time clock. The lights will operate 4,100 hours per year, or 280 hours/year less than with only the assumed baseline of time clock control. The photocell life is listed as eight years and the incremental cost is \$10 based on an average installed cost of \$9.67 for the 1994 PG&E Retrofit Express program.

The non-coincident demand savings are 0.380 kW when shutting off equipment and the coincident demand savings are 0.000 kW. Savings based on the defined lighting control scenario are projected at 106 kWh per year.

Review Results

Savings estimates appear to be reasonable. Incremental costs may be higher based on current material and installation costs. Savings may be substantially greater if controls are applied to greater numbers of lights, or less if applied to only one fixture, a common application. An in depth analysis is required for verification.

J.5.8 Time Clocks

This work paper describes timed control of exterior lighting similar to the exterior lighting controlled by photocells. These operate 4,380 or 1,248 hours less than without the time clock control. The time clock life is listed as eight years and the incremental cost is \$100 based on an average installed cost in the 2001 DEER Update Study.

The non-coincident demand savings are 0.380 kW when shutting off equipment and the coincident demand savings are 0.000 kW. Savings based on the defined lighting control scenario are projected at 474 kWh per year for all market sectors. This measure requires that time clocks must control lighting.

Review Results

Savings estimates appear to be reasonable. Savings may be substantially greater if time clock control is applied to greater numbers of lights, as is typical with time clock control. The assumption of continuous operation during the weekends should be examined, and the current codes may lead to a different baseline for hourly usage. An in depth analysis is required for verification.

J.5.9 T8 or T5 Linear Fluorescent Electronic Ballasts

This group of work papers describes use of electronic ballasts to replace energy saving magnetic ballasts for fluorescent lighting. Electronic ballasts provide better efficacies due to high frequency operation. Using more efficient lamps with electronic ballasts reduces wattage by more than the lamp wattage alone. The example scenario uses the average of two lamp and three lamp 4-ft. fixtures. The measure accounts for effects from different ballast factors. Ballast factor similarly and proportionally affect both lamp light output and electrical power input. Normally it is assumed to be unity, but for electronic ballasts may range from 0.74 to 1.2. Replaced lamps are multiplied by the electronic ballast factors. Additionally, requirements have been added to the program specifying the type of ballast

start appropriate for different applications. Coincident demand reduction is based on hours of operation for specific market sectors and sector-specific interactive effects, but apply to all market sectors. Replacement electronic ballast life is 16 years and incremental cost is listed as \$17.50 per ballast.

Review Results

Savings and cost estimates appear to be reasonable.

J.6 Refrigeration

J.6.1 Anti-Sweat Heater Controls

The baseline for this measure consists of a standard Anti-Sweat Heater (ASH), which generally runs continuously. The measure consists of installing a Pulse Modulation ASH control device that senses humidity and turns of the ASH during low humidity conditions. The work paper energy savings for this measure is based on simple heat transfer calculations with power reduction factors gathered from SCE test data. The energy savings are given per length of the cooler in feet.

Review Results

Savings estimates appear to be reasonable. Savings estimates for this measure are documented as 343 kWh/yr/linear foot and 0.04 kW/ft (with a coincident peak reduction of 0.022 kW/ft); documentation should be provided to verify this figure. A cost of \$56 per linear foot of case and a 12 year EUL appear reasonable. An in depth analysis, including a review of SCE test data used in the calculations, is required for verification.

J.6.2 Auto Closer

The baseline for this measure consists of a standard walk-in cooler or freezer door, which is assumed to be left ajar 25% of the time that the door is not intentionally open. This measure consists of replacing the door with an automatic, hydraulic-type door closer. The source of the calculations consists of ASHRAE refrigeration heat gain calculations. The work paper savings estimate is based on savings calculations and equipment and market assumptions that are over 10 years old. These assumptions include that the measure participation will include 80% coolers and 20% freezers. The savings are given per retrofitted door.

Review Results

The savings calculation methodology appears appropriate, although the measure energy savings estimates contain several assumptions, including typical cooler and freezer performance, relative proportion of cooler and freezer units, and effective hours. Savings estimates for this measure are documented as 3,535 kWh/yr/door and 0.2.279 kW/door (with

a coincident peak reduction of 0.57 kW/ft); documentation should be provided to verify this figure. A cost of \$125 per door may be low while an eight (8) year EUL appears reasonable. These assumptions should be verified in order to assess the accuracy of the savings estimates. Auto closers on glass reach in doors are not covered in this analysis.

J.6.3 Efficient Condenser - Evaporative Cooled

The baseline for this measure incorporates a prototypical supermarket which assumes parallel multiplex compressor systems with floating head pressure for serving both low-temperature and medium-temperature loads. The measure requires installation of a larger condenser and additional control mechanisms. The prototypical supermarket is defined as a 32,000 sq. ft. facility that operates 18 hours a day. The facility includes 11 display case line-ups, and 5 walk-in boxes. The work paper energy savings for these measures were estimated using DOE-2.2 models for each of the 16 California Climate Zones and for both air cooled and evaporative cooled compressors. The DOE-2.2 models are not detailed in the work paper. The energy savings are based on the size of the equipment in tons, the type of compressor (air-cooled/evaporative), and the appropriate California Climate Zone. Verification of this measure would likely require an in-depth review of the simulation models.

Review Results

Savings estimates appear to be reasonable. Additional accuracy in the savings calculations by could be obtained by comparing, and revising if necessary, the prototypical supermarkets used in the simulation with actual program participants' facilities. Savings estimates for this measure are documented as 1,316 kWh/ton to 1,812 kWh/ton depending on climate zone, with a demand savings of 0.0 kw to 0.89 kW/ton (the workpaper description and results could be more clearly described); documentation should be provided to verify this figure. An incremental cost of \$702 per ton and a 16 year EUL appear reasonable. An in depth analysis is required for verification.

J.6.4 Efficient Evaporator Fan Motors – PSC

The baseline for this measure consists of a standard efficiency shared pole evaporative fan motor on refrigerated display cases or fan coil systems of walk-in units. The measure consists of replacing the motor with a permanent-split-capacitor motor. This measure is similar to the Efficient Evaporator Fan Motors – ECM measure, although the PSC motor is not as efficient as the ECM motor, and the PSC measure had less participation. The savings estimates are based on the change in the demand of the baseline and installed motor along with associated interactive compressor savings due to the reduced heat load. The energy savings are given per length of the cooler in feet with the assumption of two motors per eight ft. case.

Review Results

The savings calculation methodology appears to be appropriate. Savings estimates for this measure are documented as 336 kWh/yr and 0.043 kW (coincident peak reduction); documentation should be provided to verify this figure. A cost of \$161 per motor and a 16 year EUL appear reasonable.

J.6.5 Evaporator Fan Controller

The baseline for this measure consists of a medium-temperature walk-in cooler with a standard evaporator unit with two 1/20 hp fans which operate continuously. The measure consists of installing a fan controller which reduces the fan speed when refrigerant is not flowing through the evaporator, to reduce energy consumption, while maintaining some flow to prevent stratification. The energy savings result from the reduced consumption of the fans as well as the interactive savings resulting from the reduced heat load. The savings calculation are based on engineering calculations and assume that the compressor operates on a 50% duty cycle and the fan speed can be reduced the remaining 50% of the time. The savings estimates are per evaporator controller (with two fans).

Review Results

Savings estimates for this measure appear reasonable. Savings estimates for this measure are documented as 1,109 kWh/yr and 0.0 kW; documentation should be provided to verify this figure. A cost of \$265 per linear foot of case and a 5 year EUL appear reasonable. An in depth analysis would require verification of the average fan size and compressor duty cycle.

J.6.6 Glass Doors - Low Temp

This measure is for a retrofit of existing equipment only. The baseline incorporates an existing open multi-deck low temperature refrigeration case. The measure consists of adding glass doors with anti-sweat heaters. The work paper energy savings for this measure is based on simple heat transfer calculations. The source of the calculations is not noted. The savings assume that the doors will be open 15% of the time and the savings result during the remaining 85% of the time. The savings are a result of the net compressor savings (excluding condenser energy and including anti-sweat heater energy losses). The energy savings are given per length of the cooler in feet.

Review Results

Savings estimates appear to be reasonable. Savings estimates for this measure are documented as 2,812 kWh/yr/door and 0.53 kW/ft (with a coincident peak reduction of 0.286 kW/ft); documentation should be provided to verify this figure. A cost of \$197 per linear foot of case and a 12 year EUL appear reasonable. An in depth analysis is required for verification

J.6.7 Glass Doors - Medium Temp

This measure is for a retrofit of existing equipment only. The baseline incorporates an existing open multi-deck medium temperature refrigeration case. The measure consists of adding glass doors with anti-sweat heaters. This measure is very similar to the measure for installing doors on a low-temperature refrigeration case, although it is less common due to the smaller energy savings. The work paper energy savings for this measure are based on heat transfer calculations, which are similar, but smaller in magnitude than those used in the glass doors for low-temperature refrigeration cases measure. The energy savings are given per length of the cooler in feet. There is some inconsistency in the variable names in the savings calculations.

Review Results

Savings estimates appear to be reasonable. Savings estimates for this measure are documented as 1,155 kWh/yr/door and 0.24 kW/ft (with a coincident peak reduction of 0.13 kW/ft); documentation should be provided to verify this figure. A cost of \$197 per linear foot of case and a 12 year EUL appear reasonable. An in depth analysis is required for verification.

J.6.8 High Efficiency Low Temperature Reach-in Display Case with Special Doors

The baseline for this measure is an existing reach-in display case with standard glass doors. This measure consists of replacing the existing fixture with a new reach-in fixture equipped with high-efficiency lighting, fan motors, and 'low/no ASH' glass doors. This measure is similar to the New Refrigeration Case with Doors – Low Temperature Case.

Review Results

Savings estimates for this measure are not documented. However, documented costs of \$700 per linear foot of door and a 16 year EUL appear reasonable.

J.6.9 New Refrigeration Case with Doors - Low Temp

The baseline for this measure incorporates an open low-temperature multi-deck case. The measure consists of replacing the case with a new case with doors. The work paper energy savings for this measure are based on heat transfer calculations similar to those used in the calculations for retrofitting existing units with glass doors. However, the new refrigeration case savings estimates include additional savings resulting from the use of energy efficiency ECM evaporator fan motors and T8 lights with electronic ballasts in the new cases. These additional savings consist of both a load reduction in the equipment and an interactive component from the reduced heat gain. The savings are a result of the net compressor,

motor, and lighting savings after accounting for the anti-sweat heater energy use. The energy savings are given per length of the cooler in feet. There appears to be some inconsistency in the variable names in the savings calculations.

Review Results

Savings estimates appear to be reasonable. Savings estimates for this measure are documented as 1,208 kWh/yr/linear foot and 0.218 kW/ft (with a coincident peak reduction of 0.118 kW/ft); documentation should be provided to verify this figure. A cost of \$100 per linear foot of case and a 16 year EUL appear reasonable. An in depth analysis is required for verification.

J.6.10 New Refrigeration Case with Doors - Medium Temp

The baseline for this measure incorporates an open medium-temperature multi-deck case. The measure consists of replacing the case with a new case with doors. This measure is very similar to the measure for replacing a low-temperature refrigeration case, although it is less common due to the smaller energy savings. The work paper energy savings for this measure are based on heat transfer calculations, which are similar, but smaller in magnitude than those used in the low-temperature new refrigeration case measure. The energy savings are given per length of the cooler in feet. There appears to be some inconsistency in the variable names in the savings calculations.

Review Results

Savings estimates appear to be reasonable. Savings estimates for this measure are documented as 581 kWh/yr/linear foot and 0.108 kW/ft (with a coincident peak reduction of 0.058 kW/ft); documentation should be provided to verify this figure. A cost of \$100 per linear foot of case and a 16 year EUL appear reasonable. An in depth analysis is required for verification.

J.6.11 Night Covers

The baseline for this measure is a vertical stand-up medium-temperature refrigerated case or a tub (coffin) low-temperature refrigeration case installed in a facility that is typically closed and inactive at night (e.g. smaller, independently owned grocery stores). The measure consists of installing a film or blanket cover during night hours to insulate the case. The savings calculation consist of engineering calculation with assumptions of the covers infiltration and radiation heat gain reductions. These assumptions are not documented. The energy savings are based on the type of case, vertical or horizontal, and given per length of the cooler in feet.

Review Results

Savings estimates appear to be reasonable. Savings estimates for this measure are documented as 148 kWh/yr/linear foot for vertical covers and 59 kWh/yr/linear foot for horizontal covers (with a peak reduction of 0.0 kW/ft); documentation should be provided to verify this figure. A cost of \$9.25 per linear foot and a 5 year EUL appear reasonable. An in depth analysis is required for verification.

J.6.12 Special Doors with Low/No ASH Controls

The baseline for this measure consists of a new cooler/freezer with a standard door that includes an ASH system. The measure consists of upgrading the new cooler/freezer with new low-heat/no-heat doors with either reflective treated glass and/or gas filled panes. The savings calculations consist of engineering calculations with assumptions of the cooling load reduction resulting from the special doors. The source of the calculations and load reduction assumptions is not noted. The savings are given per linear ft. (width) of door with a minimum door height of 57".

Review Results

The savings calculation methodology appears appropriate, although the measure energy savings estimate is based on an undocumented load reduction assumption. Savings estimates for this measure are documented as 749 kWh/door and 0.049 kW/ft (with a coincident peak reduction of 0.015 kW/ft); documentation should be provided to verify this figure. A cost of \$77 per linear foot of door and a 16 year EUL appear reasonable. Additional information, preferably in the form of sample or standardized testing data, is required to assess the accuracy of the savings estimates.

J.6.13 Vending Machine Controller

The baseline for this measure is a standard vending machine with lights that operate continuously and refrigeration equipment that cycle continuously. The measure consists of retrofitting the vending machine with a controller, which includes an occupancy sensor, to turn off light and vendor controller when no one is present. The controller also uses logic to periodically power up the machine so the compressor maintains proper product temperature. The work paper states that the energy savings are based on a field survey of 62 machines and includes a reference to the source. The savings estimates are given per unit installed.

Review Results

Savings estimates for this measure are documented as 1,590 kWh/yr; documentation should be provided to verify this figure. An in depth analysis would require review of the referenced study. Costs or \$200 per controller are reasonable. An EUI of three years may be shorter than the actual life.

J.6.14 Suction Line Insulation

The baseline for this measure consists of a bare copper suction line between 0.375' and 1.5" diameter. The measure consists of installing flexible closed-cell nitrite rubber insulation (3/4" for medium temperature and 1" for low temperature applications). The source of the calculations consists of ASHRAE refrigeration heat transfer calculations. The work paper savings estimate is based on savings calculations and equipment and market assumptions that are over 10 years old. These assumptions include an estimated 5,700 equivalent full-load hours of operation and measure participation consisting of 80% medium-temperature applications and 20% low-temperature applications. The energy savings are given per length of the cooler in feet.

Review Results

The savings calculation methodology appears appropriate, although the measure energy savings estimates contain several assumptions, including typical compressor efficiencies, relative proportion of medium-temperature and low-temperature units, and effective hours. Savings estimates for this measure are documented as 18.4 kWh/yr/linear foot (with a peak reduction of 0.0 kW/ft); documentation should be provided to verify this figure. A cost of \$1.73 per linear foot and an 11 year EUL appear reasonable. Averages are used to calculate these figures (based on pipe size and application). These assumptions should be verified in order to assess the accuracy of the savings estimates. As these suction lines are usually insulated at installation, the assumption of worn verses bare insulation may be more appropriate for baseline conditions.

J.7 Water Heating

J.7.1 Storage Water Heater

This measure is for the replacement of an existing small to medium sized gas storage water heaters used for domestic hot water applications. It does not apply to non-storage (instantaneous) water heaters, pools or spas, or industrial process water uses. Applicable building/business types include (but are not limited to) offices, restaurants, retail, schools, colleges, hotels, motels, and recreational facilities. The work paper energy savings calculations were developed on modeling that was based on average equipment characteristics for SoCalGas customer participants for Express Efficiency storage water heater measures (larger units with efficiencies of 82+%; all small units) during PY 2001. The work paper includes an average rated input of 251 MBtuh per unit, an average savings of 440 therms per unit, an incremental cost of \$1,701 per unit, and an average lifetime of 15 years.

Review Results

Savings estimates appear to be reasonable, based upon a usage factor of 20% and an efficiency increase of 10%, due to thicker amounts of tank insulation and larger heat exchange areas. Additional accuracy in the savings calculations could be obtained by reevaluating the average equipment characteristics for customer participants, since the current characteristics are based on 2001 figures. Savings estimates may be more reasonable for SCG and SDGE customers than for PGE customers. Work papers for all three IOUs state that the energy savings calculations were based on the average equipment characteristics of a SCG customer. This maybe valid for estimating energy savings for SCG and SDGE, but it may not be for PGE for a number of reasons, including cooler groundwater or higher use due to cooler air temperatures in the areas that PGE serves. The space heating demands may be greater for a typical PGE customer.

J.7.2 Instant Water Heaters

This measure is for the replacement of existing gas powered storage water heaters with an instantaneous tankless gas water heaters (i.e., neither new construction nor fuel switching applications are eligible). Only instantaneous water heaters used for domestic hot water applications qualify. Such units feature sufficiently large efficient burners to heat water immediately to commercial temperature requirements. Instantaneous water heaters thereby provide users with "endless" supplies of heated water. Such units are highly energy efficient, as standby losses are effectively eliminated. These measures are applicable to any small or medium commercial domestic hot water application; cannot be used for process end uses. Examples of building/business types include (but are not limited to) offices, restaurants, retail, schools, colleges, hotels, motels, and recreational facilities. Instantaneous water heaters must have an energy factor of .63+ (<=200 Mbtuh units) or thermal efficiency of 82+% (>200 Mbtuh units). Cost effectiveness calculations applicable to PY 2002 Express Efficiency instantaneous water heater equipment measures have been developed based on the 2001 DEER study, comparable cost manuals (e.g., R.S. Means), and the CEC instant water heater equipment database.

Review Results

Savings estimates appear to be reasonable based on a 10% savings factor and 20% usage factor for large units above 200 Mbtuh and medium sized units between 75.1 Mbtuh and 200 Mbtuh. However, savings may be overstated for smaller units below 75 Mbtuh with a reported average rating of 42 Mbtuh. In fact, savings were listed as 222 therms per year for small units, while the savings for the average 139 Mbtuh medium sized unit was listed as 196 therms per year. Additional accuracy may be calculated based on more current information and data on instant hot water heaters since the heat exchanging methods and technology may

have improved. Furthermore, average usage values may vary for different buildings or business types; therefore, this value may also be weighted by sector.

J.7.3 Space Heating Boiler

This measure applies to gas-for-gas equipment replacement (i.e., neither new construction nor fuel switching applications are eligible) of space heating boilers. These boilers are pressure vessels that transfer heat to water for use primarily in space heating applications. Boilers used for pools or spas do not qualify. These measures are applicable to any small or medium commercial boiler application used primarily for space heating and cannot be used primarily for process end uses or for domestic hot water. Energy efficient units often feature high efficiency and/or low NO_x burners, and typically have features such as water tubes, power burners, relatively large heat exchange surfaces, and/or utilize heat recovery from stack gases. Typical applications for this measure include (but are not limited to) offices, restaurants, retail, schools, colleges, hotels, motels, and recreational facilities. Boilers must have a combustion efficiency of 82+% (large units) or AFUE of 77+% (small steam units) or 82+% (small water units). The work paper energy savings calculations were developed based on average equipment characteristics for SoCalGas customer participants for Express Efficiency space heating boiler measures (those units with efficiencies of 82+%) during PY 2001. These include an average rated input of 1,269 of 1,269 per unit, an average savings of 814 therms per unit, and an average lifetime of 20 years.

Review Results

Savings estimates appear to be reasonable for SCG and SDGE, but not PGE. The work papers state that the energy savings calculations were based on the average equipment characteristics of a SoCalGas customer. This maybe valid for estimating energy savings for the SoCalGas and SDGE customers, but it may not be valid for PGE customers, because the air temperature is cooler in the areas that PGE serves. Therefore, the space heating demands may be greater for a typical PGE customer. However, based upon 20% usage for 50% of the year, savings with the average size boiler listed above are approximately 7% of the total usage. This appears reasonable for most locations, but may be higher for areas in northern California and inland areas.

J.7.4 Process Boilers (Including Direct Contact Water Heaters)

This measure applies to gas-for-gas equipment replacement (i.e., neither new construction nor fuel switching applications are eligible) of process boilers that are used primarily for industrial applications. These measures are applicable to any small or medium commercial boiler application used primarily for industrial processes and cannot be used primarily for space heating uses or for domestic hot water. The main applicability is in the industrial sector, but also includes commercial laundry, dry cleaning, agricultural and miscellaneous

process uses. Boilers must have combustion efficiency as installed of 82+%. Work paper savings have been developed based on average characteristics among customer participants in the SoCalGas Process Energy Consumption boiler measure during PY 2001. The size was listed as 3,093 Mbtuh per average unit and an annual savings of 7,074 therms.

Review Results

Savings estimates appear to be overstated based upon average usage of 50% for 30% of the entire year (corresponding to single shift operation) of the typical size boiler listed above. Boiler size and use must be quantified. Additional accuracy in the savings calculations could be obtained by re-evaluating the average equipment characteristics and usage for customer participants, since the current characteristics are based on 2001 figures in only one SoCalGas program

J.7.5 Spray Nozzles

This measure applies to pre-rinse spray valves that reduce the flow of water from 2.5 gpm to 1.5 gpm. Savings are computed in therms for varying hours per day usage for the valves. As an example, the calculation methodology for usage of 4 hours per day is provided in the workpapers as:

240 gal//day x 363 days/yr x 8.33 lbs/ga x 55 degrees F delta T / 0.70 efficiency / 100,000 Btu / therm = 570 therms per year saved.

Review Results

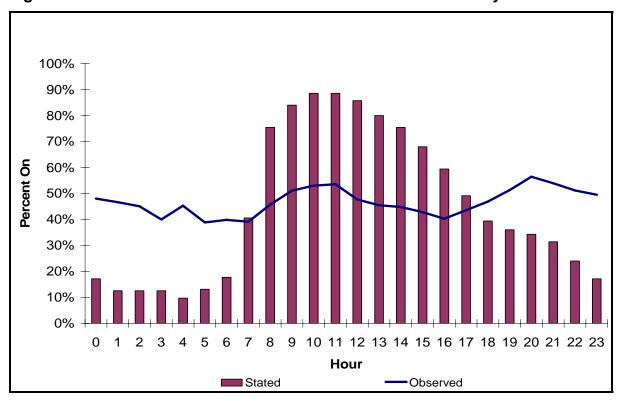

Energy savings of 285 therms per year for two hours per day of use are reasonable. This is the minimum daily usage stipulated, and should be verified. There are ancillary water efficiency benefits. Costs of \$60 per valve are reasonable.
